1 EXECUTIVE SUMMARY

Natural precipitation provides the sole source of water supply for the Big Bear Valley (Valley), and is relied on for potable groundwater supplies, replenishing Big Bear Lake and Stanfield Marsh, and supporting the rare and diverse habitat and species in the Valley. Drought conditions and a long-term decline in precipitation trends have led the local water management agencies to investigate opportunities for supplemental water supplies, which are extremely limited due to its isolated location at the top of the watershed. Currently, wastewater generated within the Valley undergoes preliminary and secondary treatment and is discharged outside of the watershed to irrigate alfalfa fields in the Lucerne Valley, located approximately 20 miles north of the Valley.

The Big Bear Area Regional Wastewater Agency (BBARWA), Big Bear City Community Services District (BBCCSD), Big Bear Lake Department of Water and Power (BBLDWP), and Big Bear Municipal Water District (BBMWD) (collectively, the Project Team) recognize that retaining recycled water in the watershed for beneficial use would significantly increase the sustainability of local water supplies. The Project Team has partnered to develop a project that will recover this lost water resource and keep the water in the Valley for beneficial reuse.

In 2016, the Bear Valley Water Sustainability Study evaluated four (4) alternatives for reuse, including distribution of tertiary treated recycled water for landscape irrigation and several groundwater recharge alternatives using advanced purified water. However, these alternatives address only the potable water supply component of the Valley's water needs and do not provide sufficient benefits to warrant the local investment so they have not been pursued.

The Project Team is currently evaluating an additional water reuse alternative that provides more widespread benefits to the Valley, known as the Lake Alternative. The Lake Alternative includes the following uses and benefits:

- High quality water will be discharged to the Stanfield Marsh Wildlife and Waterfowl Preserve, providing a consistent water source to sustain habitat and increase education opportunities for the community and visitors
- Water from the Marsh provides new inflow to Big Bear Lake to augment lake levels, enhance recreational opportunities and aquatic habitat and support water quality improvements
- High quality water will be discharged to Shay Pond to sustain habitat for the federally listed Unarmored Threespined Stickleback fish, which is currently sustained using potable water
- During extended dry periods, water from Big Bear Lake will be pumped to Sand Canyon to recharge the groundwater basin to strengthen the sustainability of the groundwater basin
- During wet periods, excess water could be stored locally as snow, providing flexibility to further enhance winter recreation, reduce spills from Big Bear Lake, augment spring runoff and increase groundwater recharge. Water could also be used to irrigate the local golf course in the summer, if desired.

- Additional inflow may enable BBMWD to modify their current Big Bear Lake management strategy to minimize spills and optimize releases to enable additional water to be captured downstream for recharge of the San Bernardino Basin, rather than discharged to the ocean.

Implementation of the Lake Alternative will require significant upgrades to BBARWA's wastewater treatment plant (WWTP) to produce high quality water that meets stringent discharge requirements for Big Bear Lake, particularly for nutrients (specifically phosphorus and total inorganic nitrogen) and total dissolved solids (TDS). To achieve the anticipated effluent limits, it is anticipated that BBARWA will need to implement a series of upgrades to existing unit processes and integrate new unit processes:

- Upgrade the extended aeration process through retrofit of the existing oxidation ditches to optimize biological nitrification-denitrification (NDN) and phosphorus removal.
- If needed, incorporate chemical precipitation of soluble phosphorus through addition of a metal salt within the activated sludge tankage, upstream of clarification.
- New NDN process to reduce inorganic nitrogen concentrations. This process may consist of a biologically active filter with sand or synthetic media, or biological reactors designed specifically for nitrogen and phosphorus removal.
- New low pressure filtration, such as microfiltration (MF) or ultrafiltration (UF), to reduce flocculated or colloidal solids upstream of the reverse osmosis (RO) process.
- New RO to reduce TDS concentration and nutrient concentrations.
- Disposal of brine stream generated from the RO process, such evaporation ponds, with or without brine minimization.

The preliminary design capacity of the treatment upgrades is 2.2 mgd, which corresponds with the 10-year average annual flow to the WWTP. It is assumed that any flows in excess of 2.2 mgd would be treated to a secondary level and discharged to Lucerne Valley, similar to the existing discharge method. Accounting for seasonal and annual flow variations and the volume disposed of as brine, the preliminary estimate of yield from the Lake Alternative is 1,950 AFY.

The Lake Alternative is a multi-component project that achieves the Project Team's goal of recovering a lost water supply to increase the sustainability of local water supplies to benefit the entire Valley. It is also the most cost-effective alternative that has been identified, in terms of unit cost of water recovered for various beneficial uses. The Project Team is continuing to collaborate with regulators and other stakeholders to refine these benefits, identify potential additional benefits and identify a path toward a cost effective and multi benefit for sustainable water in the Big Bear Valley.

2 INTRODUCTION

2.1 BACKGROUND

The Big Bear Valley (Valley) is located in the San Bernardino Mountains of San Bernardino County, California. The area includes approximately 135 square miles within a 12-mile long valley surrounded by mountain ridges and rugged slopes. Land surface elevations range from 6,000 to 9,900 ft and the area is entirely surrounded by the San Bernardino National Forest. Big Bear Lake (Lake) lies within the Valley and has a surface area of approximately 10 square miles and 23 miles of shoreline and is connected to the Stanfield Marsh Wildlife and Waterfowl Preserve. The Valley is home to approximately 23,000 full time residents. The area is primarily residential with some commercial uses, and experiences an influx of part-time population and vacationers enjoying the four season recreational facilities within the valley. In 2016, it is estimated that 8.3 million people visited the Valley. Due to the recreational nature of the Valley economies, occupancy within the valley fluctuates seasonally, typically peaking in July and at the lowest level during the winter. Based on the United States Census American Community Survey 2010-2014 data, all of the developed areas of the Valley are considered Disadvantaged or Severely Disadvantages Communities due to Median Household Incomes (MHI) less than 80% or 60%, respectively, of the statewide MHI, as defined in the California Public Resources Code Section 75005.

Natural precipitation provides the sole source of water supply for the Valley, and is relied on for potable groundwater supplies, replenishing the Lake, and supporting the rare and diverse habitat and species in the Valley. Drought conditions and a long-term decline in precipitation trends have led the local water management agencies to investigate opportunities for supplemental water supplies, which are extremely limited due to its isolated location at the top of the watershed. Currently, wastewater generated within the Valley undergoes preliminary and secondary treatment and is discharged outside of the watershed to irrigate alfalfa fields in the Lucerne Valley, located approximately 20 miles north of the Valley.

2.2 PROJECT TEAM

The Project Team is comprised of the Big Bear Area Regional Wastewater Agency (BBARWA), Big Bear City Community Services District (BBCCSD), Big Bear Lake Department of Water and Power (BBLDWP), and Big Bear Municipal Water District (BBMWD). The Project Team recognizes that retaining recycled water in the watershed for beneficial use would significantly increase the sustainability of local water supplies to benefit the entire Valley and has partnered to jointly fund and prepare this report. The following sections provide a brief introduction to each agency.

2.2.1 BBARWA

BBARWA was formed in March 1974 to conduct a study to develop a plan for wastewater management within the greater Valley region. A subsequent 1975 Wastewater Facilities Plan was prepared which identified the need to provide centralized, environmentally friendly wastewater conveyance, treatment and disposal for the BBARWA service area.

The BBARWA service area includes the entire Valley (79,000 acres) and is served by three separate collection systems: City of Big Bear Lake, representing approximately 47% of the connections, and BBCCSD, representing approximately 48% of the connections, and County of San Bernardino Service Area 53B (CSA 53), representing approximately 5% of the connections. Each of these member agencies maintains and operates its own wastewater collection system, and delivers wastewater to BBARWA's interceptor system for transport to the BBARWA Regional Wastewater Treatment Plant (WWTP).

2.2.2 BBCCSD

BBCCSD was created in 1966 by a formation and consolidation election and initially provided solid waste collection, fire protection and street lighting services. In 1967, the former Big Bear Mutual Service Company voted to relinquish ownership and operation of their water system to BBCCSD. Currently BBBCSD's services include water, wastewater collection, fire protection & emergency medical services, solid waste collection, and street lighting services. BBCCSD's water service area includes Big Bear City and portions of San Bernardino County. BBCCSD's wastewater collection area includes Big Bear City and portions unincorporated communities such as Sugarloaf, Erwin Lake, Whispering Forest, and Moonridge.

2.2.3 BBLDWP

BBLDWP was formed in 1989 with the purchase of the retail water system from Southern California Water Company and currently provides water service to the City of Big Bear Lake, located along the south side of Big Bear Lake, as well as the unincorporated communities of Fawnskin, which lies to the north of the lake, and Sugarloaf, Erwin Lake and Lake William areas, which lie on the east side of the Valley.

The City of Big Bear Lake provides wastewater collection services within the city, while BBCCSD and CSA 53B provide wastewater collection services within BBLDWP's water service area that lies outside the city limits.

2.2.4 BBMWD

BBMWD, formed in 1964, is an independent special district that is responsible for the overall management of Big Bear Lake. The primary responsibilities of BBMWD are:

- Stabilization of the level of Big Bear Lake by managing the amount of water released to Bear Valley Mutual
- Watershed/water quality management
- Recreation management
- Wildlife habitat preservation and enhancement
- Bear Valley Dam and Reservoir maintenance

2.3 PRIOR STUDIES & PURPOSE

There is a long legacy of exploring water reuse opportunities in the Big Bear Valley for a variety of beneficial uses including wildlife habitat, landscape irrigation, surface water discharge, and groundwater recharge. Water reuse opportunities in the Valley were first investigated in 1964 and evaluations have continued intermittently since BBARWA was formed in 1974.

Most recently, in 2016, the Bear Valley Water Sustainability Study (2016 Study) evaluated four (4) alternatives for reuse, including distribution of tertiary treated recycled water for landscape irrigation and several groundwater recharge alternatives using advanced purified water. The 2016 Study concluded that groundwater recharge at two different recharge sites (Greenspot and Sand Canyon) was the highest ranked alternative due to a lower unit cost relative to the other alternatives and higher volume of water retained in the Valley.

Due to stringent water quality requirements and the challenge of disposing of the brine waste generated from the treatment process upgrades, full-scale groundwater recharge in the Valley is still a costly option. Although local potable groundwater water supplies are impacted by drought, conservation efforts in the past few years have maintained the total potable consumption below the safe yield of the groundwater basin. While the availability of high quality recharge water would benefit the water agencies by providing a supplemental drought proof source of supply when needed during future extended drought periods, continuous large volumes of recharge water are not needed to sustain local groundwater supplies at this time. A full-scale groundwater recharge project addresses only the potable water supply component of the Valley's water needs and does not provide sufficient benefits to warrant the high cost. For these reasons, full scale groundwater recharge in the Valley is not being pursued at this time.

The purpose of this report is to evaluate an additional water reuse alternative that more widespread benefits to the Valley; the subject alternative is presented in Section 2.5. This report repeats some relevant background information contained in the 2016 Study for context. Additional background information and detail on the prior alternatives evaluated can be found in the 2016 Study. Appendix C to the 2016 Study includes a timeline summarizing the evolution of wastewater management in the Valley from 1935 to 2003 as well as a partial list of documents related to water reuse in the Valley, as of April 2005.

2.4 PROJECT GOALS AND OBJECTIVES

The goal of the Project Team is to partner to recover a lost water resource, close the water loop, and keep the water in the Valley for beneficial reuse. This goal will be achieved through development of a multi-benefit water reuse project that:

1. Augments natural recharge for water supply sustainability
2. Protects the rare and diverse habitat and species in the Valley
3. Promotes a thriving community through enhanced recreation

2.5 THE LAKE ALTERNATIVE

The project alternative evaluated in this report is referred to as the Lake Alternative and includes upgrades to the WWTP to produce high quality water for the following uses and benefits:

- High quality water will be discharged to the Stanfield Marsh Wildlife and Waterfowl Preserve (Marsh), providing a consistent water source to sustain habitat and increase education opportunities for the community and visitors

- Water from the Marsh provides new inflow to the Lake to augment Lake levels, enhance recreational opportunities and aquatic habitat and support water quality improvements
- High quality water will be discharged to Shay Pond to sustain habitat for the federally listed Unarmored Threespined Stickleback (Stickleback) fish, which is currently sustained using potable groundwater
- During dry periods, Lake water will be pumped to Sand Canyon to recharge the groundwater basin to strengthen the sustainability of the groundwater basin during extended droughts
- During wet periods, excess water could be stored locally as snow using existing snow making infrastructure. This provides flexibility to further enhance winter recreation, reduce spills from the Lake, augment spring runoff and increase groundwater recharge. The existing snow making pump and pipeline can also be used to deliver irrigation water to the Bear Mountain Golf Course in the summer, if desired. The water demand for the Bear Mountain Golf Course is estimated to be 120 AFY (1).
- Additional inflow into the Lake may enable BBMWD to modify the current Lake management strategy to minimize spills and flood control releases and optimize releases to enable additional water to be captured for recharge of the San Bernardino Basin, rather than discharged to the ocean.

The Project Team is conducting ongoing outreach to a variety of potential stakeholders within the Valley and the greater Santa Ana River watershed to collaboratively refine these benefits and identify potential additional benefits that could be achieved through implementation and management of the Lake Alternative.

The Lake Alternative will require significant upgrades to the treatment process at the WWTP to meet stringent discharge requirements for the Lake, as discussed in subsequent sections of this report.

3 WATER SUPPLIES AND MANAGEMENT

This section provides a brief overview of current water supplies and water management practices in the Big Bear Valley to provide context for the development of recycled water supplies. Currently, the sole source of water supply in the Valley is groundwater from the Big Bear Valley Groundwater Management Zone (Basin). BBMWD manages Big Bear Lake but the water agencies do not have surface water rights and imported water is not available in the Valley due to lack of infrastructure to the isolated location. Additional information about potable water supplies can be found in the BBCCSD 2015 Urban Water Management Plan (UWMP) and BBLDWP 2015 UWMP.

3.1 BIG BEAR VALLEY GROUNDWATER MANAGEMENT ZONE

The Basin lies in the northeastern portion of the Santa Ana River Watershed and is currently not adjudicated. The Basin is roughly 14 miles long from east to west and 7 miles wide from north to south. Big Bear Lake and Baldwin Lake are located in the middle of the Basin. Surface drainage within the Basin flows to one of the two lakes, mostly Big Bear Lake. Big Bear Lake empties on the west into Bear Creek, which is a tributary to the Santa Ana River. Additional information on the management of surface water in Big Bear Lake is discussed in Section 3.3.

The Basin is primarily composed of unconsolidated alluvium and is divided into upper, middle and lower aquifers; where the upper and middle aquifers are the primary producers. Based on the drainage system, the Basin is divided into 16 hydrologic subunits with the main tributaries including Grout Creek, Van Dusen Canyon, Sawmill Canyon, Sand Canyon, Knickerbocker Creek, Metcalf Creek, and North Creek. The Basin and subunits are presented in Figure 3-1.

The Basin is naturally recharged from percolation of precipitation, runoff and underflow from fracture rock formations; with groundwater levels that generally correlate with annual fluctuations of precipitation. Storage capacity of the Basin is estimated by DWR at 42,000 AFY with the maximum perennial yield estimated at 4,800 AFY (7). In addition to the municipal water purveyors, there are numerous private wells throughout the Basin serving properties that are not connected to a public water system.

BBLDWP and BBCCSD manage and monitor the Basin. Through the Groundwater Monitoring and Management Plan, BBLDWP contributes to Basin management by conducting monthly monitoring of 18 non-pumping monitoring wells and approximately 40 production wells, bi-annual Technical Review Team meetings, and has established conservation levels based on groundwater levels and trends in key wells. BBCCSD also manages the groundwater level and water quality by conducting monthly monitoring in 11 non-pumping monitoring wells and 13 production wells, monthly monitoring of surface flow in Van Dusen Creek, Shay Creek and Green Canyon Creek, and has established action criteria for average groundwater levels across the BBCCSD service area that are tied to conservation stages and measures. Conservation efforts have helped to keep annual groundwater production less than the perennial yield of the Basin. The Basin is not currently identified by DWR to be in overdraft condition. (4) (8)

3.1.1 Sustainable Groundwater Management Act

In 2014, California passed the Sustainable Groundwater Management Act (SGMA), which established a framework for sustainable, local groundwater management. The California Department of Water Resources (DWR) is responsible for implementing the law and supporting local agencies to achieve sustainable groundwater management. DWR identified the Basin as a Medium Priority Basin and SGMA requires Medium Priority Basins that are not in critical overdraft to be managed under a Groundwater Sustainability Plan (GSP) by January 21, 2022. The GSP will be developed and implemented through formation of the Bear Valley Basin Groundwater Sustainability Agency (BVBGSA), which is a Joint Powers Authority (JPA) comprised of the four agencies on the Project Team.

In December 2017, the BVBGSA applied for a Sustainable Groundwater Planning Grant to fund the preparation of the GSP. The GSP is anticipated to be completed by 2020 and will leverage existing data sources and management actions that have been utilized by BBLDWP and BBCCSD in the past. The workshops held throughout the development of the GSP will provide a venue to engage relevant stakeholders in a dialogue to build on this foundation and develop similar management actions to meet sustainability goals for the Basin as a whole.

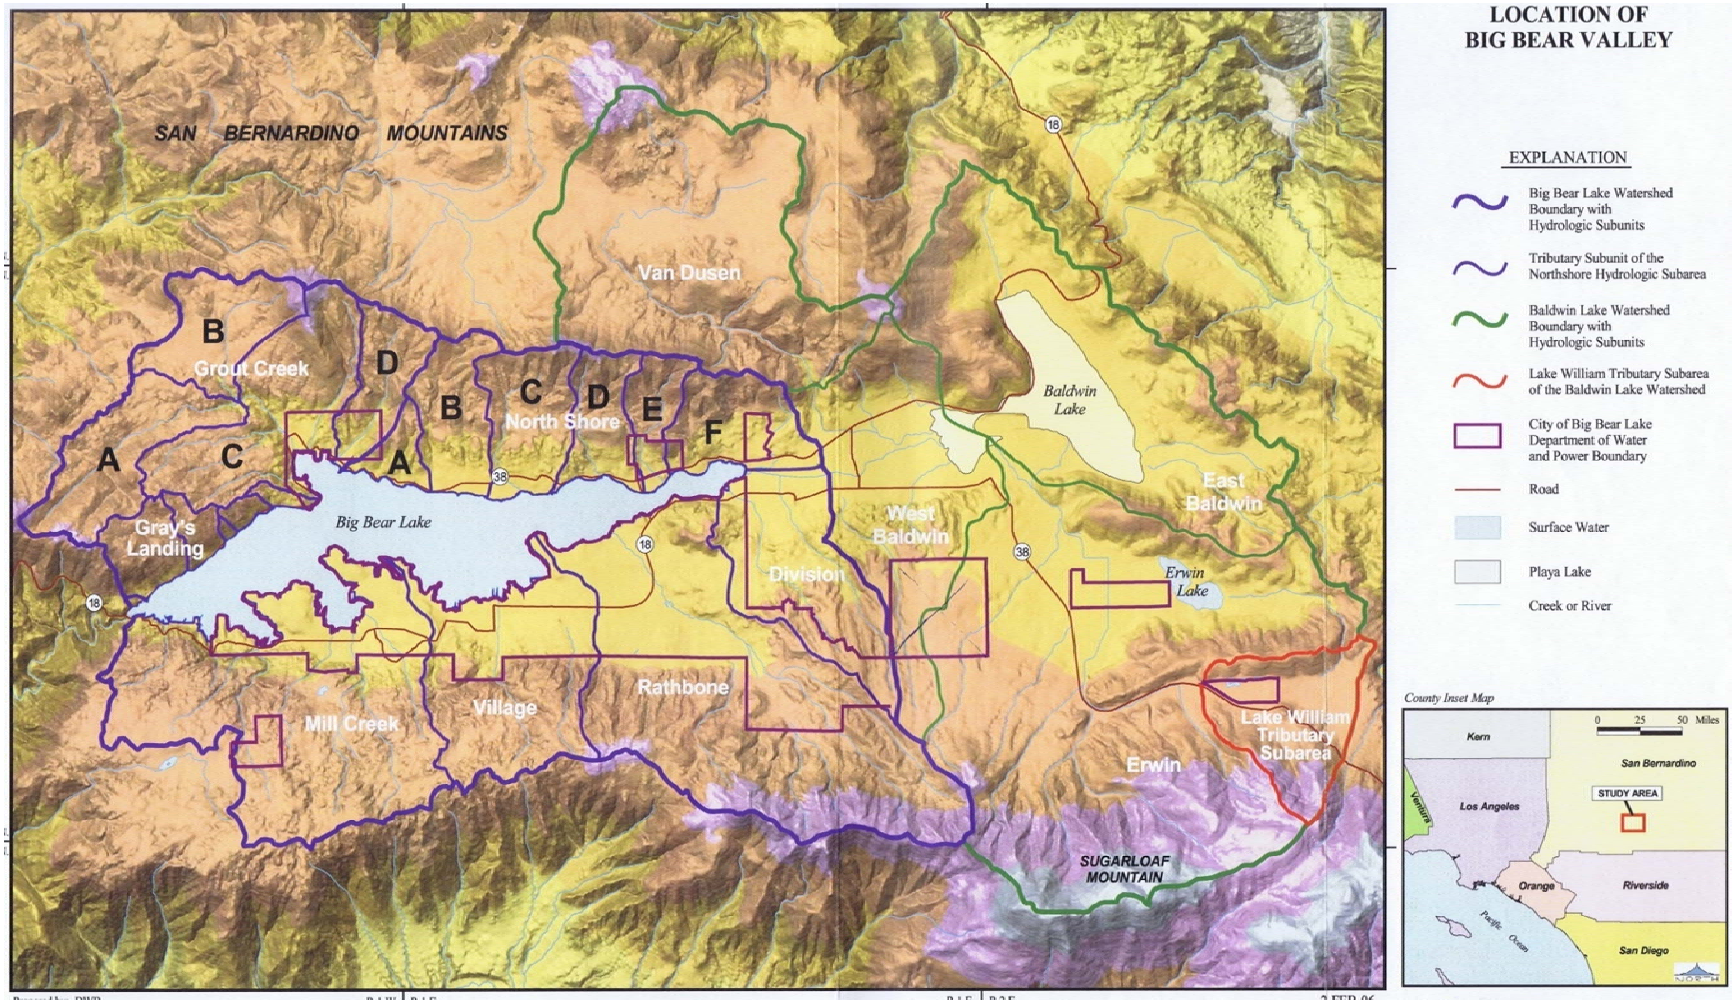

Figure 3-1. Big Bear Valley Groundwater Basin and Subunits (9)

3.2 WATER DEMAND

The BBLDWP service area is primarily residential with commercial accounts making up 5% and industrial making up less than 1% of the total accounts. BBCCSD serves only residential accounts. The projected water demands for BBLDWP and BBCCSD area are presented in Table 3-1. The historical and projected water demands for each water agency along with the total demands for the agencies are presented in Figure 3-2. These estimates do not include water used from private wells, which was estimated to be approximately 169 AFY in the BBLWDP 2006 Water Master Plan (7).

Table 3-1. Water Demand Projections for Bear Valley Water Agencies (AFY)

Water Agency	2015	2020	2025	2030	2035
BBLDWP[1]	2,095	2,169	2,246	2,326	2,408
BBCCSD[2]	940	1,163	1,220	1,281	1,344
Total	3,035	3,332	3,466	3,607	3,752

2. BBCCSD 2015 UWMP

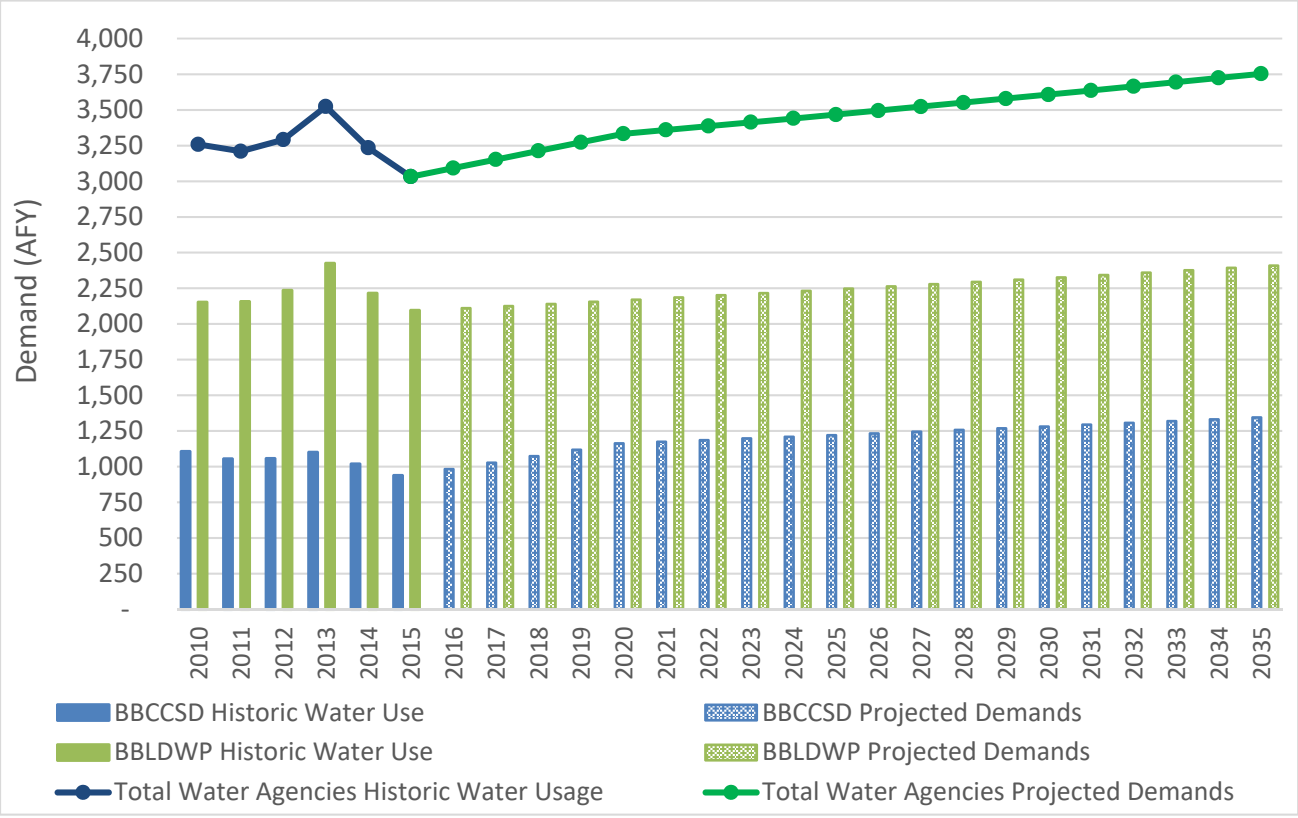

Figure 3-2. Historic and Projected Water Demands

3.3 BIG BEAR LAKE WATER MANAGEMENT

This section describes the key management practices and documents that govern the management of the water in Big Bear Lake. This information is also presented graphically in Figure 3-4.

3.3.1 The 1977 Judgement

The Big Bear Dam was originally constructed to provide water storage for Bear Valley Mutual Water Company (Mutual), which was formed in 1903 by the citrus growers of the Redlands/Highland area to ensure water supply for irrigation needs. The historic operation of the Big Bear Lake (Lake) as an irrigation reservoir resulted in drastic fluctuations in lake levels, which conflicted with the goals of BBMWD and the community of Big Bear Valley. A legal conflict over the water rights and management of the lake was ultimately settled out of court through the 1977 Judgement. Under the terms of this judgement, BBMWD purchased the lake bottom, Bear Valley Dam, and the right to utilize and manage the surface of Big Bear Lake from Bear Valley Mutual. Bear Valley Mutual retained a storage right and ownership of all water inflow into the Lake (1). Mutual has the right to request Lake releases as may be reasonably necessary to meet the requirements of Mutual's stockholders, not exceeding 65,000 AF in any ten (10) year period.

3.3.2 In-Lieu Water and Lake Release Policy

The 1977 Judgment allows BBMWD to maintain a higher water level in the lake by delivering water to Mutual from an alternate source of water. This alternate source of water, referred to as In-Lieu Water, comes mainly from the State Water Project through a contract executed in 1996 with San Bernardino Valley Municipal Water District (Valley District), a State Water Contractor. This In-Lieu Agreement provides that:

- BBMWD shall make Lake releases to meet the demands of Mutual when such releases are consistent with BBMWD's Lake Release Policy (described below)
- Whenever Lake releases under the Lake Release Policy are not sufficient to meet Mutual's demands, Valley District shall provide In-Lieu Water to Mutual to meet the remainder of their demands
- BBMWD shall pay Valley District a fixed annual fee, which is escalated annually based on BBMWD's assessed value. In 2017, BBMWD's In-Lieu payment to Valley District was approximately $1,400,000.

BBMWD's current Lake Release Policy was adopted in 2006 provides guidance on how Mutual demands will be met depending on the Lake level.

- When the Lake is in the top 4 feet, Mutual's demands will be met with Lake releases
- When the Lake is between 4 and 6 feet below full, Lake releases will be made in the months of November through April and In-Lieu Water will be obtained from May to October
- When the Lake is more than 6 feet below full, In-Lieu Water will be obtained

3.3.3 Snow Making Withdrawals

BBMWD currently has a contract with the Big Bear Mountain Resorts, allowing the withdrawal of an allocated amount of water from the Lake to use for snow making purposes. Currently, Big Bear Mountain Resort is authorized to withdraw a maximum of 11,000 acre-feet (AF) of water from the Lake over a 10-year rolling period, not exceeding 1,300 AF in any single year. It is calculated that half of the water withdrawn from the lake is returned as runoff (1).

3.3.4 Net Wastewater Exports

The 1977 Judgement required that, beginning in 1986, any net export of water to an area of the Upper Bear Creek Watershed that is not tributary to the Santa Ana Watershed would be transferred from BBMWD's Lake Account to Mutual's Lake Account, as discussed in Section 3.3.6. Because water reclamation was not implemented by 1986, a net wastewater export occurs annually and is calculated as the difference between the wastewater that leaves the Big Bear Lake watershed and the water that is imported into the Big Bear Lake Watershed from the Baldwin Lake Watershed. Groundwater that is produced within the Big Bear Lake Watershed and returned to the sewer after use is treated at the BBARWA WWTP (located in the Baldwin Lake Watershed), then discharged to Lucerne Valley; this water is exported from the Big Bear Lake Watershed. Groundwater that is produced in the Baldwin Lake Watershed by BBLDWP and BBCCSD and served to customers within the Big Bear Lake Watershed is imported into the Big Bear Lake Watershed. In 2016, the net wastewater exported from the Big Bear Lake Watershed was 848 AF.

3.3.5 Fish Protection Releases

In 1995, the State Water Resources Control Board (SWRCB) issued Order No. 95-4, which requires BBMWD and Mutual to release water from the Lake for fishery protection in Bear Creek. Sufficient water must be released from the Lake to maintain a seven-day average flow of 1.2 cubic feet per second (cfs) and minimum average daily flow of 1.0 cfs in Bear Creek no more than 500 feet downstream of its confluence with West Cub Creek, referred to as Station A. SWRCB Order No. 95-4 also requires sufficient releases to maintain a minimum flow of 0.3 cfs approximately 300 feet downstream of the toe of the dam, referred to as Station B. The dam releases required to maintain these minimum flows vary by month and by hydrologic year type (normal, above normal or below normal precipitation).

3.3.6 Watermaster Accounting

The 1977 Judgment requires the establishment of a Watermaster to maintain three basic accounts:

BBMWD's Lake Account. A detailed account to reflect actual operation of the Lake by BBMWD.

Mutual' s Lake Account. A corollary account that simulates the effect of Mutual's operation if Mutual had owned the Lake, the In-Lieu Program was not in place, and there was no net wastewater export from the Big Bear Lake Watershed.

Basin Make-up Account. An account of BBMWD's annual and cumulative obligation for Basin Make-up Water in the San Bernardino Groundwater Basin to offset any deficiencies in recharge as a result of BBMWD's Lake operation. In 2016, the Basin Make-up Account had an ending balance of 27,120 AF. This positive amount means that there has been an increase in groundwater recharge in the San Bernardino Basin as a result of the BBMWD operation of the Lake.

Figure 3-3 depicts the actual Lake levels under BBMWD's operation compared to the simulated Lake operation by Mutual as shown by the balance of Mutual's Lake Account. In 2016, BBMWD's operation of the Lake resulted in a Lake level 14.43 feet higher than it would have been under Mutual's operation.

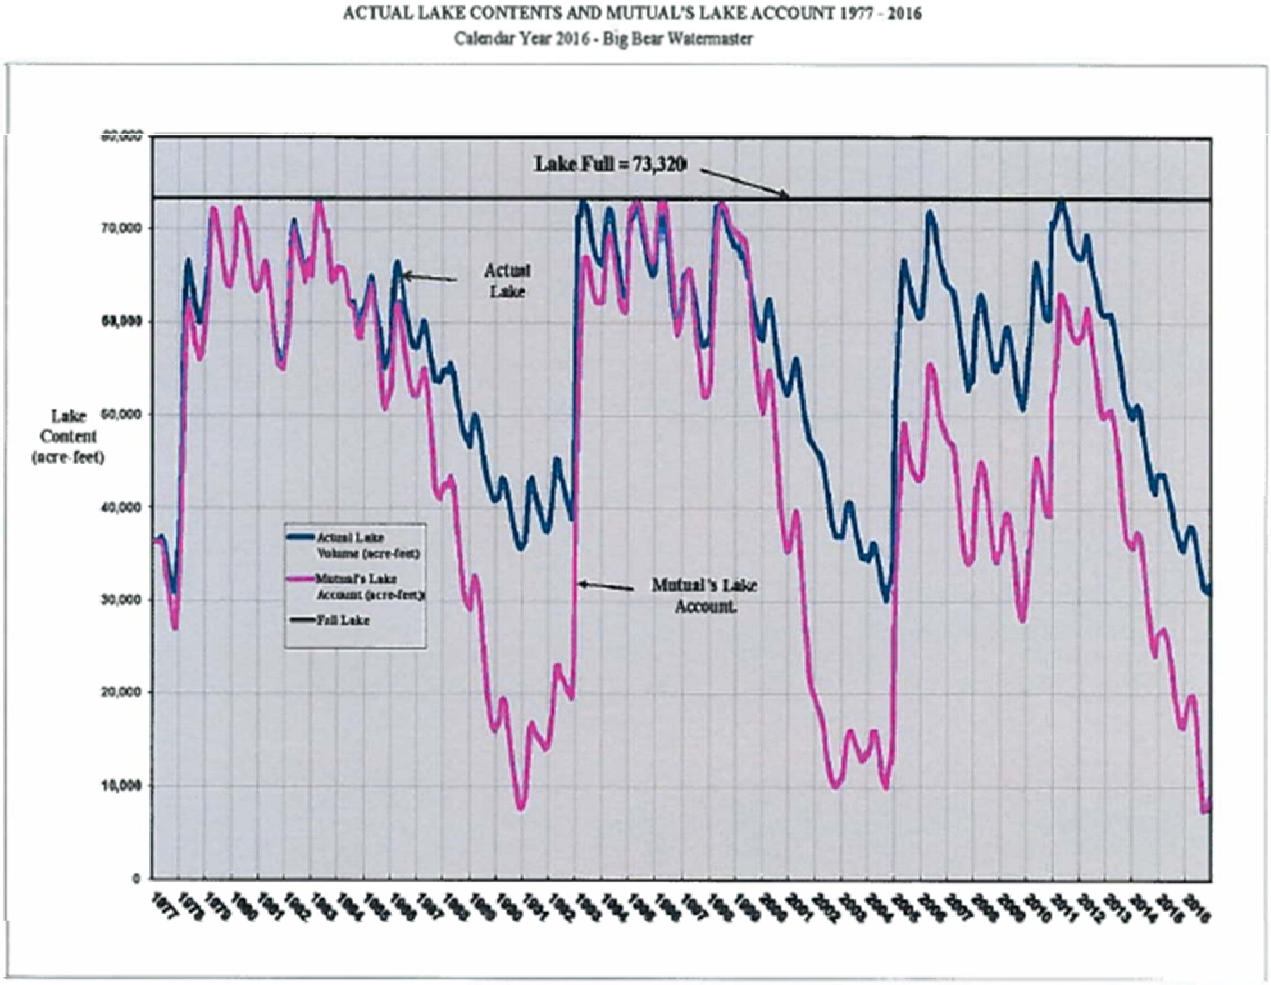

Figure 3-3. Actual Lake Levels and Mutual's Lake Account Comparison, 1977 - 2016 (5)

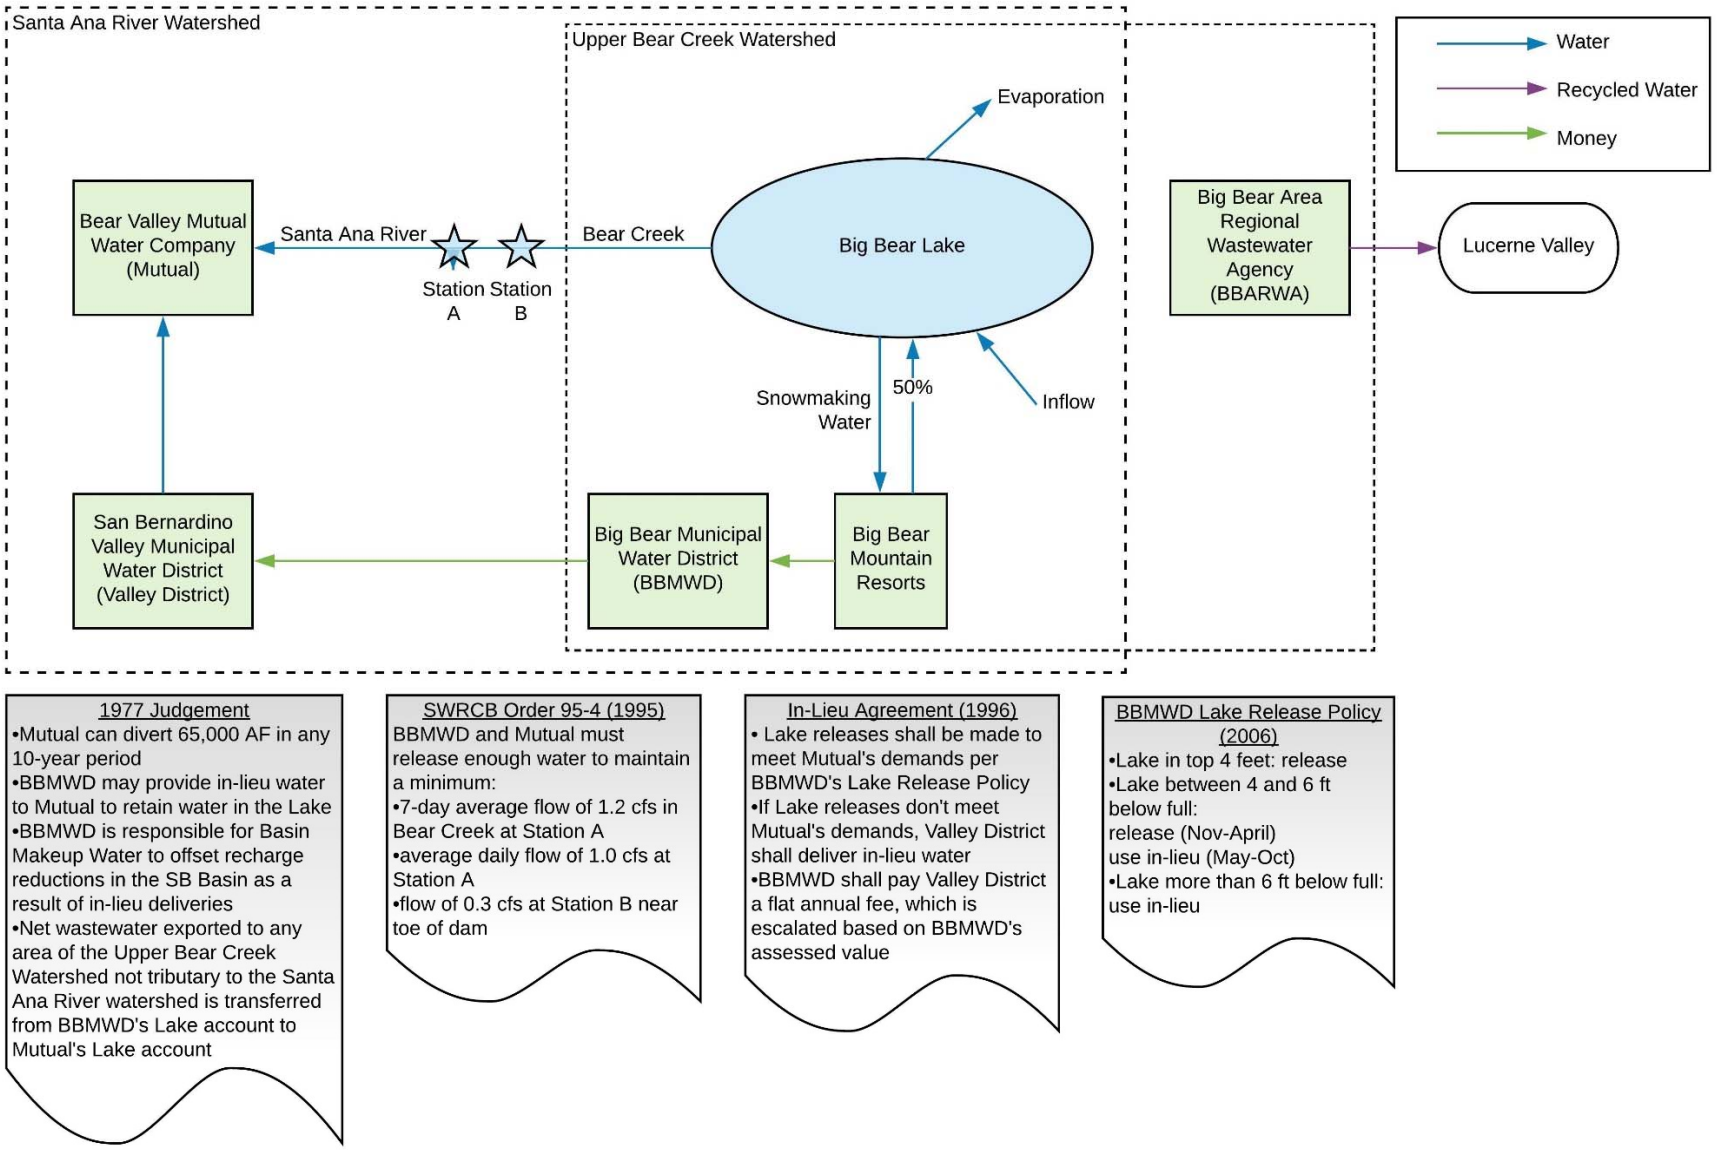

Figure 3-4. Big Bear Lake Management Framework

4 WASTEWATER CHARACTERISTICS AND FACILITIES

BBARWA owns and operates a 4.9 million gallon per day (MGD) capacity WWTP located just south of Baldwin Lake on the east side of the Valley. In 2016, the WWTP treated approximately 1.9 MGD of municipal wastewater collected from BBCCSD, the City of Big Bear Lake and CSA 53 in Fawnskin.

4.1 EXISTING AND PROJECTED WASTEWATER FLOWS

The influent flows to BBARWA's WWTP are comprised of three components:

- Flow from full-time residential homes
- Flows due to tourism, commercial activities and part-time residential homes
- Flows from Infiltration and Inflow (I/I) due to precipitation

These components create a seasonal variation in the wastewater flows treated at the plant. Based on full-time residency rates from BBCCSD and BBLDWP and the number of full-time dwelling units reported by Bear Valley Electric, BBARWA's 2010 Sewer Master Plan (2010 SMP) estimated that the full-time residential rate is 38% (2).

The tourism season is largely concentrated in the months of December through April due the local ski resorts; this period also corresponds with higher precipitation and increased flows due to I/I. The months of June and July also see a slight rise in tourism due to Lake recreation activities. Average daily flows and the seasonal variation during the 10-year period from 2007 to 2016 (which included a wet and dry cycle) are shown in Figure 4-1. The average daily flow for this 10-year period is approximately 2.2 MGD and the maximum month flow is 5.5 MGD.

The 2010 SMP estimated the future sewer flows based on future population and equivalent dwelling unit (EDU) projections utilizing the constant sewer load index of 172 gallons per day (gpd) for full time residential EDUs. The 2010 SMP assumes the full-time EDUs will increase at an annual rate of 0.8% over a 20-year period based on a long-term average. Assuming the full-time residence rate remains at 38% and that I/I will be consistent with the previous average, the 2010 SMP projects that the average annual sewer flows will increase to 2.7 MGD by 2030. However, the 2010 SMP flow projections did not account for reduced sewer loads due to recent water conservation so future flows will likely be significantly lower than projected.

If the Lake Alternative is implemented, it is recommended that the future flow projections be updated as part of the preliminary design phase to inform the design capacity for treatment upgrades based on realistic flows based on current water use trends.

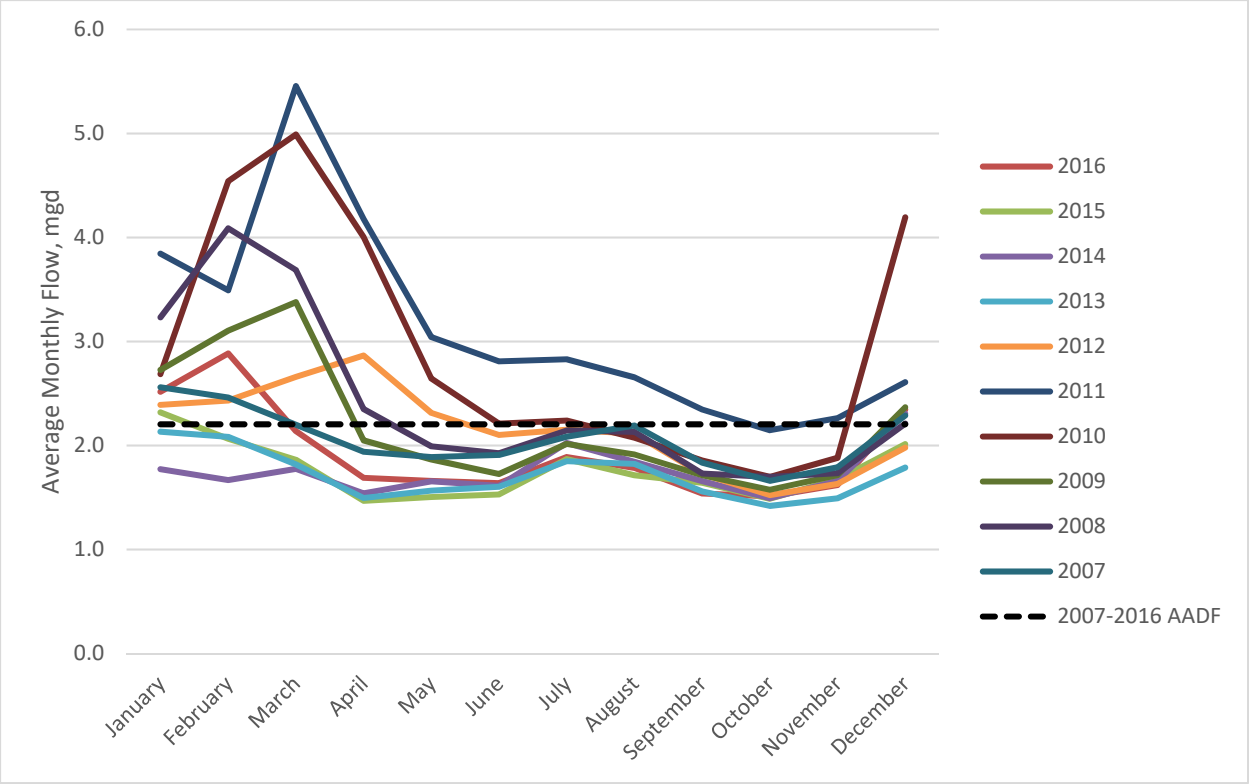

Figure 4-1. 10-Year Average Daily Flows by Month (2007-2016)

4.2 EXISTING FACILITIES AND DISCHARGE REQUIREMENTS

BBARWA's WWTP is located on a 93.5-acre lot. The WWTP process components occupy 11.2 acres and the remaining 82.3 acres include storage ponds and evaporation ponds. Influent flows are conveyed through three BBARWA operated sewer mains and lift stations to the plant. The WWTP currently provides preliminary and secondary treatment. Table 4-1 summarizes the WWTP's treatment processes and the process flow diagram is depicted in **Figure 4-2**.

BBARWA recently completed several upgrades to the sludge dewatering process. Heat exchangers were installed on the existing generator to capture waste heat; hot water from the heat exchangers is used to heat the floor of the lined drying bed. A 315 foot by 60 foot metal building was also constructed to cover the lined drying bed so that the dewatering process could operate year round.

BBARWA's WWTP generates its own electricity using three natural gas generators that can be run in parallel: two 250 KW Cummins generators and one Waukesha generator with a rating of 600 kilowatts for a total generating capacity of 1100 kilowatts. BBARWA only generates the energy needed to operate the WWTP and Administration Building and typical generation is in the range of 225,000 - 350,000 kilowatt-hours (kW-hr) per month. In 2015, total energy generation was 3,100,216 kW-hr. Natural gas consumption was 43,544 million British Thermal Units (MMBTU) or 435,440 therms. BBARWA also has a connection to the Bear Valley Electric utility system that is used to run its pumping stations and can serve as an emergency backup power supply for the WWTP.

Table 4-1. BBARWA's WWTP Treatment Process

Treatment Process[1]	Description
Preliminary Treatment	Consists of bar screens, grit removal and disposal of solids
Secondary Biological Treatment	Consists of oxidation ditches which use mechanical aeration to achieve organic material stabilization, nutrient removal and pathogen reduction. Solids production is minimized by the Cannibal® Solids Reduction System, through use of a side-stream interchange bioreactor with aeration controlled by the ORP level.
Secondary Sedimentation Treatment	Consists of clarifiers to settle solids. Waste activated sludge (WAS) is pumped to a dissolved air floatation (DAF) system
WAS Thickening	Consists of a DAF system that skims sludge for sludge dewatering. Filtrate is returned to oxidation ditches.
Sludge Dewatering[2]	Sludge is dewatered using a belt press and dried in a building with heated floors that utilize waste heat from a generator. The building allows sludge to be dried year-round. The dry solids are hauled to a composting facility in Redlands.

Notes:
1. Descriptions obtained from the 2005 BBARWA Recycled Water Master Plan unless otherwise noted.
2. Obtained from BBARWA's website - http://bbarwa.org

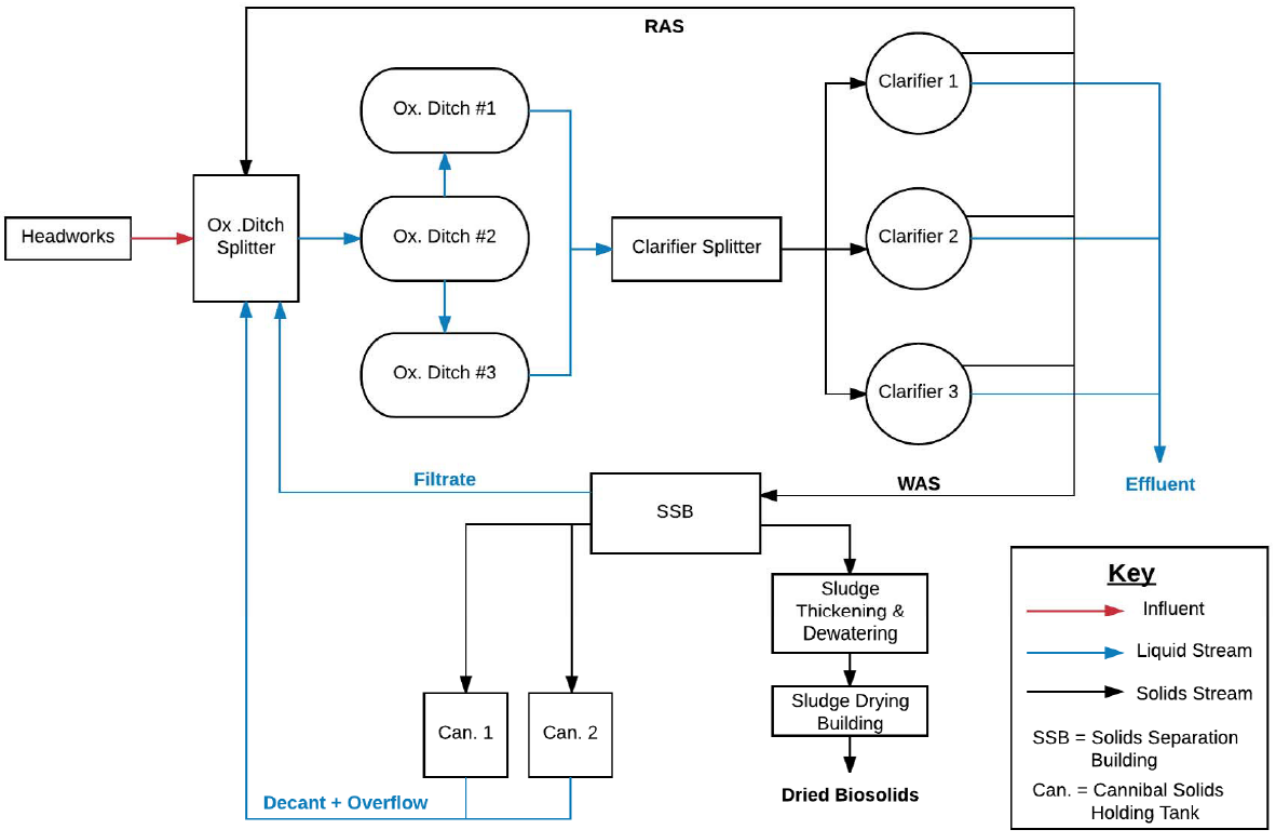

Figure 4-2. BBARWA WWTP Process Flow Diagram

4.2.1 Existing Discharge Requirements

The wastewater stream that is treated by the WWTP consists of sewage generated from urban land uses. There are no significant sources of major industrial waste or processing water treated by the facility (2). The WWTP discharge is currently regulated by the Santa Ana Regional Water Quality Control Board (RWQCB) under Waste Discharge and Producer/User Water Recycling Requirement (WDR) Order No. R8-2005-0044 (Santa Ana WDR) issued on June 24, 2005. There are three permitted discharge locations, summarized in Table 4-2. Discharge Point 001 for irrigation in Lucerne Valley, is located within the Colorado River Basin Region and is regulated by Colorado River Basin RWQCB WDR Order No. R7-2016-0026 (Colorado WDR), issued on June 30, 2016.

Treated secondary effluent is discharged to a 480-acre site in Lucerne Valley (LV Site) for irrigation of fodder and fiber crops that are used as feed for livestock. Use of recycled water for crop irrigation at the LV Site began in 1980 and 100% of the WWTP effluent is currently discharged to the LV Site. Figure 4-3 depicts the location of BBARWA's existing recycled water distribution facilities and the LV Site, approximately 20 miles north of the Valley. Discharge Points 002 and 003 are not currently used.

Table 4-2. WDR Order No. R8-2016-0044 Discharge Points

Discharge Point	Effluent Description	Receiving Water/Disposal Site	Recycling Reuse
001[1]	Secondary effluent w/o disinfection	Storage Ponds in Lucerne Valley	Irrigation in Lucerne Valley
002	Secondary effluent with disinfection	State surface water (Storage pond in Baldwin Lake) and Big Bear Valley Groundwater Management Zone	Construction and wildlife habitat
003	Tertiary effluent with disinfection	Big Bear Valley Groundwater Management Zone	Irrigation

Notes:
1. The Colorado River Basin Regional Water Quality Control Board (Region 7) regulated the use of the recycled water in the Lucerne Valley (WDR Order No. R7-2016-0026).

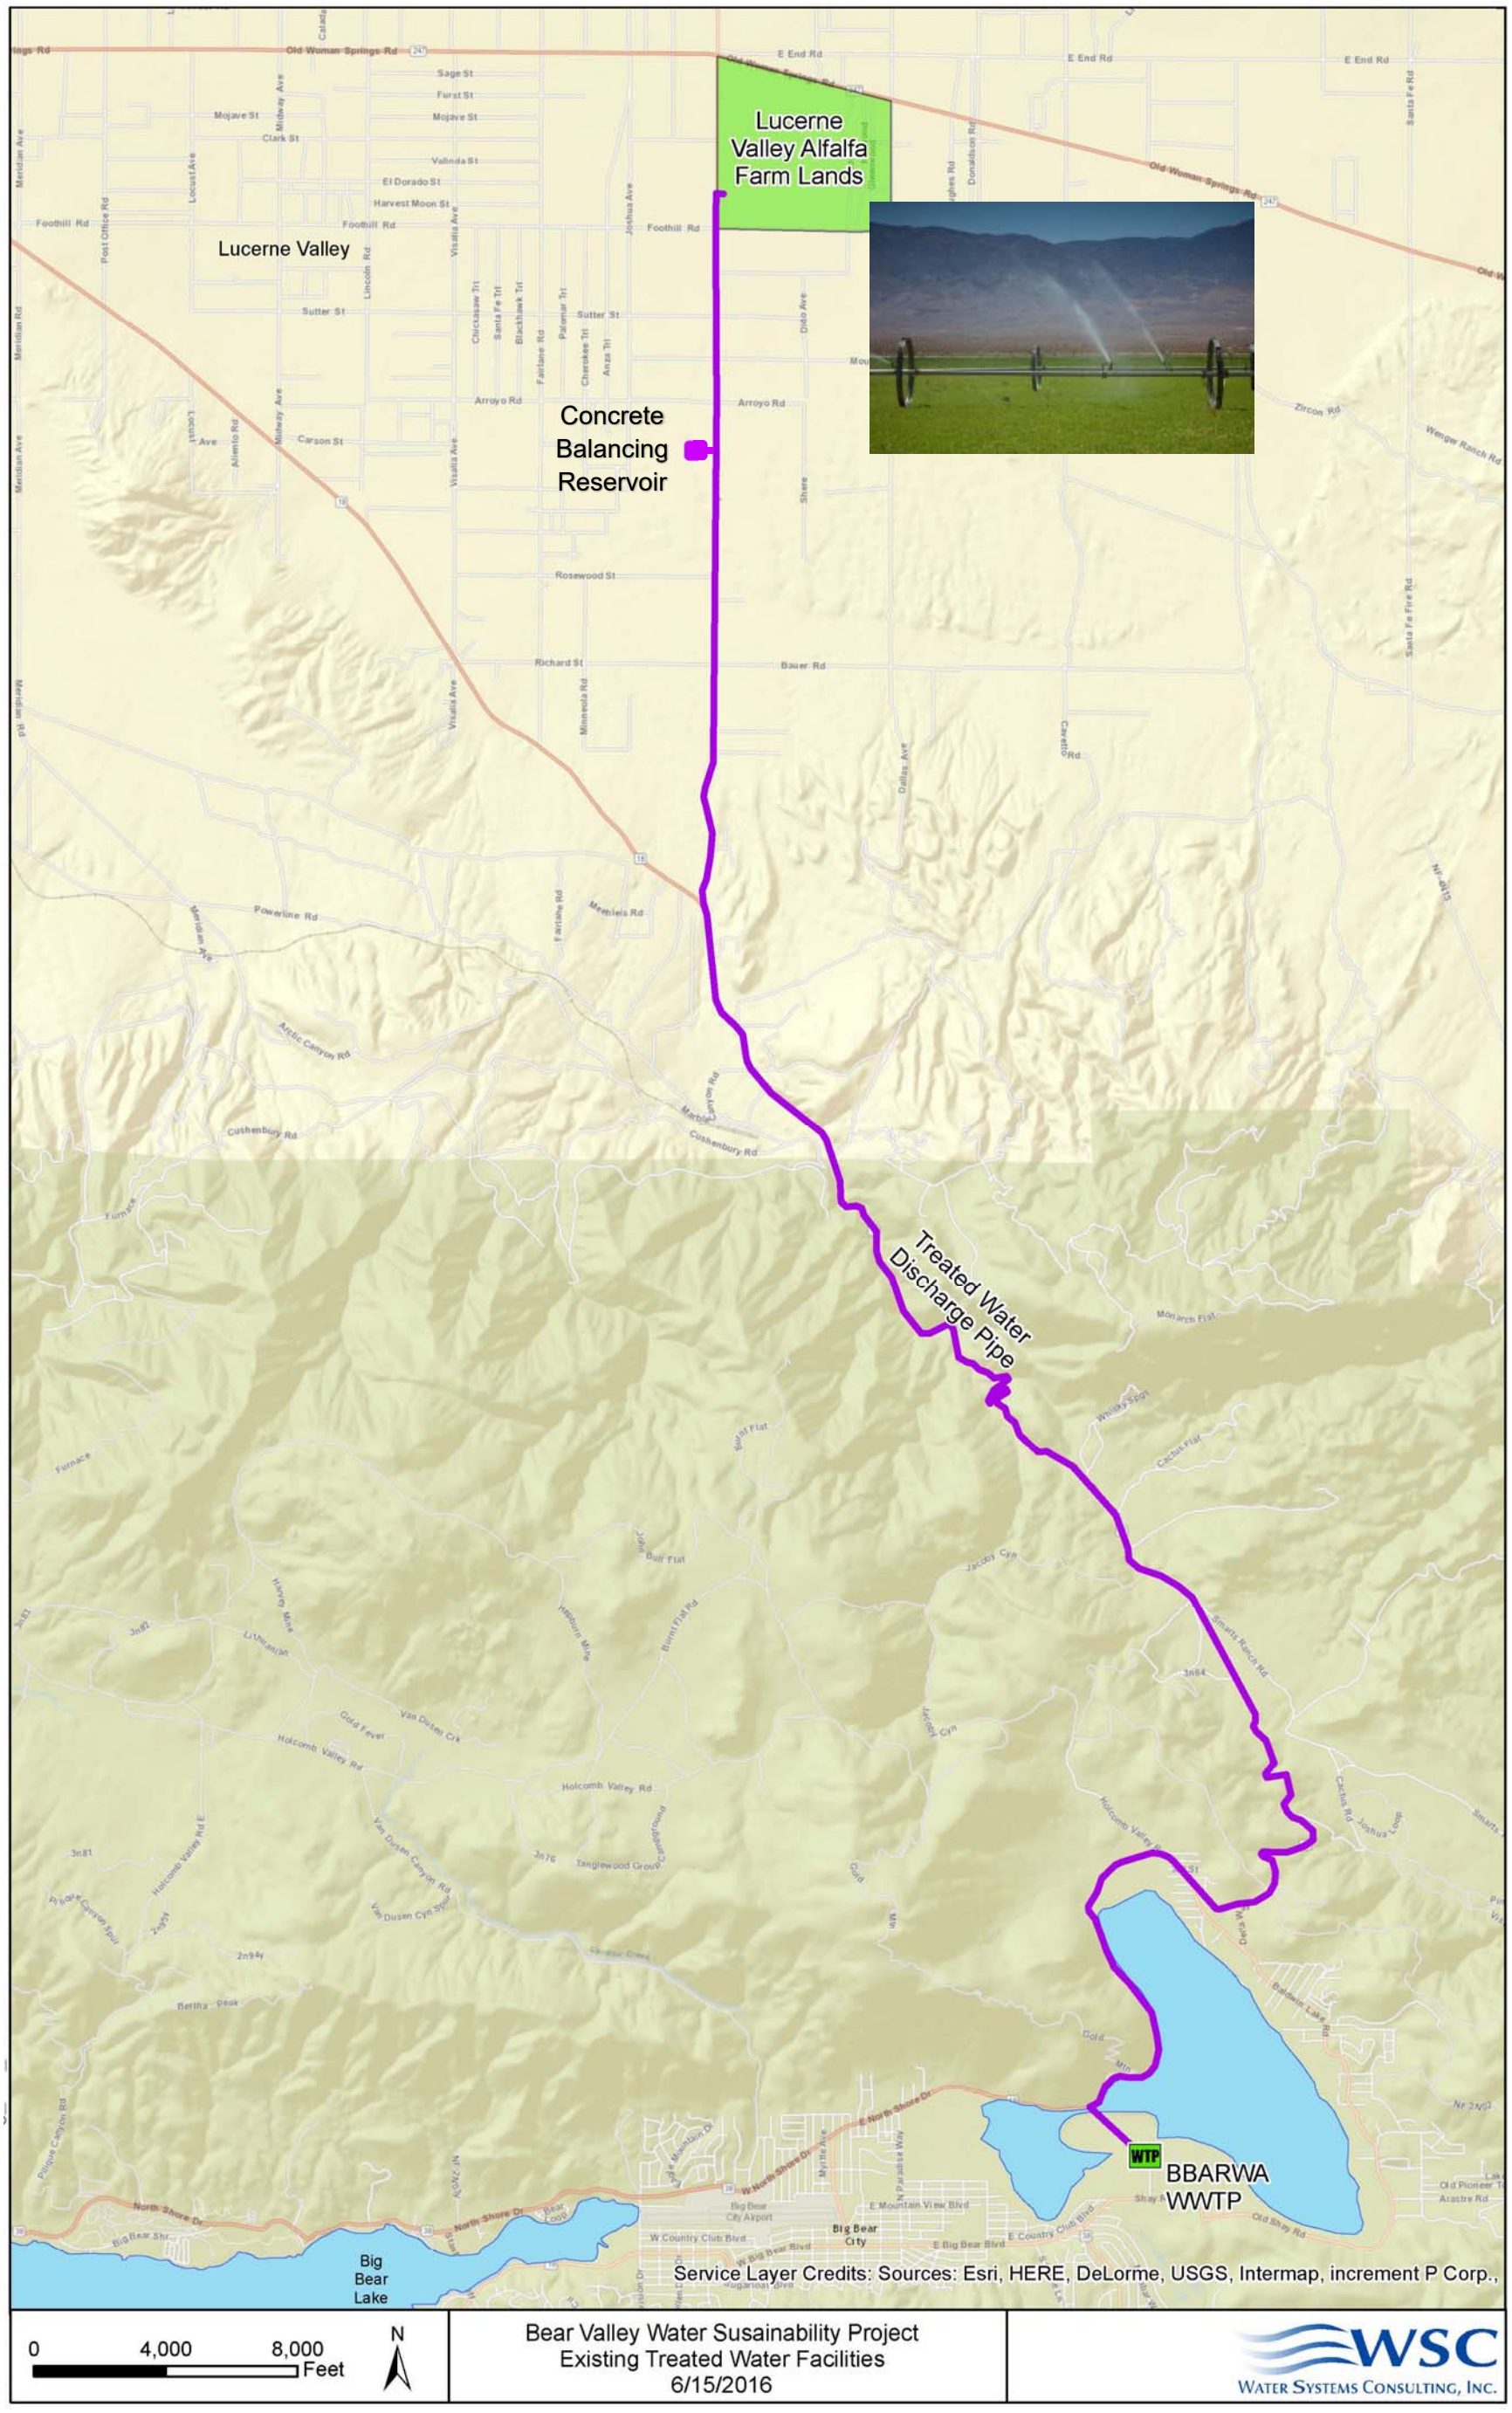

Figure 4-3. Existing Recycled Water Facilities

The effluent requirements for conventional pollutants for recycled water discharged to the LV Site contained within the Colorado WDR are presented in Table 4-3 and a summary of the actual effluent quality in 2015 is presented in Table 4-4.

The previous Colorado WDR that regulated this discharge (Board Order 01-156) included a Total Dissolved Solids (TDS) limit of a maximum of 400 mg/L above the domestic source water. The WWTP discharge was always well within compliance with this requirement. The recently updated WDR requires BBARWA to provide a technical report in the form of a study that analyzes the impacts to groundwater in the vicinity of the LV Site by the discharge and an evaluation of water quality trends. The results of the study will be used to establish an appropriate effluent limitation for TDS. BBARWA submitted this report to the Colorado River Basin RWQCB in December 2017 with a recommendation that the prior TDS limit remain unchanged. The Colorado River Region RWQCB has not yet provided feedback on the report or an indication of whether the TDS effluent limitation will be changed. At this time, a substantive change in the TDS limit is not anticipated and treatment upgrades are not anticipated to be required to remain in compliance with this WDR. A copy of BBARWA's two WDR permits are attached in Appendix A.

Table 4-3. Discharge Limits for LV Site

Parameter	Units	30-Day Mean	7-Day Mean	Maximum Daily
Biochemical Oxygen Demand (BOD_5)	mg/L	30	45	-
Total Suspended Solids (TSS)	mg/L	30	45	-
Chloride	mg/L	60	-	80
Sulfate	mg/L	60	-	80
Boron	mg/L	-	-	0.75
Total Nitrogen	mg/L	10	-	-
pH	pH units	Between 6.0 - 9.0 at all times		

Table 4-4. 2015 BBARWA WWTP Effluent Quality – Annual Average

Parameter	Value	Units
TDS	453	mg/L
BOD_5	6	mg/L
TSS	13	mg/L
Chloride	56	mg/L
Sulfate	43	mg/L
Phosphorus	2.3	mg/L
Total Inorganic Nitrogen (TIN)	4.6	mg/L
pH	7.12 – 8.09	pH units

5 RECYCLED WATER MARKET ANALYSIS UPDATE

A brief description of previous alternatives evaluated in the 2016 Study was discussed in Section 2.3. This section provides additional details on the recycled water uses envisioned for the Lake Alternative only.

In 2017, the Project Team collaborated to identify a new Lake Alternative that maximizes the use of existing infrastructure to reduce project costs while keeping most or all of the treated water in the Valley for a variety of beneficial uses. The following uses are anticipated to be included in the Lake Alternative and are discussed in more detail in subsequent sections.

- Continuous water supply to Stanfield Marsh Wildlife and Waterfowl Preserve
- Continuous water supply to Big Bear Lake
- Continuous water supply to Shay Pond Unarmored Threespined Stickleback habitat
- Periodic groundwater recharge in Sand Canyon during dry periods
- Periodic storage in the watershed as snow during wet winter periods
- Irrigation water for Big Bear Golf Course
- Potential water supply for downstream users when water exceeds needs in the Valley

5.1 STANFIELD MARSH AND BIG BEAR LAKE

Discharge to Stanfield Marsh was considered in the 2016 Study as a potential groundwater recharge location; however, it was not pursued because a prior study stated that the bottom of the Marsh contains a clay layer that would prevent sufficient percolation into the surrounding groundwater basin. Discharge to the Marsh is being re-evaluated as part of this study due to the benefits that a new consistent water source would provide to the wildlife in the Marsh, and because it provides a means to supplement inflow in the Lake as well.

The Stanfield Marsh Wildlife and Waterfowl Preserve began a transformation in 1982 when BBMWD, working with the California Department of Fish and Wildlife, dredged basins, laid culvert pipes to connect to the Lake, and planted the shoreline, followed by numerous other enhancements in subsequent years. The Marsh is now a scenic 145-acre nature park that includes a gazebo, walking paths, and two boardwalks that extend out into the Marsh so that visitors can observe the wildlife in, under and around the water. The Marsh is home to rare and diverse species of birds, fish, amphibians, and mammals. In the center of the Marsh, there is an island that was constructed to provide a safe haven for waterfowl, including a moat-like barrier to make it difficult for predators to reach it, even when water levels are low. Informational placards installed at the Marsh educate visitors on the diverse wildlife and BBMWD has plans to install several additional placards, such as those as shown in Figure 5-1, to increase educational opportunities and awareness of the value of the Marsh to the local ecosystem.

Figure 5-1. Informational Placards at the Marsh Provide Educational Opportunities for Visitors

Rainfall and snowmelt are the only sources of water for the Marsh so the water level varies from season to season and throughout longer hydrologic cycles. During wet periods, the Marsh is a thriving wildlife preserve. During extended drought conditions, the water level recedes dramatically, the boardwalks extend over dry soil, and the wildlife become scarce. This condition is shown in Figure 5-2, which was taken in September 2016 following the recent multi-year drought.

Figure 5-2. Aerial View of the Dry Marsh, September 2016

High quality recycled water would provide a new, drought proof source of inflow to stabilize the water levels and sustain habitat in the Marsh even during dry periods.

Water from the Marsh will also provide new inflow into the Lake to augment Lake levels. Preliminary model analysis performed by BBMWD indicates that new inflow into the Lake could increase Lake levels by as much as 7 feet in 10 years, depending on the volume of new inflow. As discussed in Section 3.3.2, in-lieu water is obtained to meet Mutual's Lake demands when Lake levels are below 4 and 6 feet from full, depending on the month. With the additional inflow, Lake levels will be in the top 4 feet more often, which will reduce in-lieu water needs.

Increased Lake levels will also enhance recreational opportunities by enabling BBMWD to reduce closures of boat ramps due to low water levels during dry periods. More wetted shoreline is anticipated to improve aquatic habitat and the additional inflow will provide BBMWD with additional flexibility in managing Lake releases, creating an opportunity to improve water quality in the Lake.

The California Code of Regulations Title 22 (Title 22) establishes acceptable uses of recycled water and provides that disinfected tertiary recycled water may be used as a source of supply for nonrestricted recreational impoundments, which are water bodies where no limitations are imposed on body-contact water recreational activities.

In 2000, BBARWA was issued a National Pollutant Discharge Elimination System (NPDES) permit (Santa Ana Region Board Order No. 00-12), which included the Marsh and a proposed new Stickleback habitat in Baldwin Lake as authorized discharge points, subject to construction of tertiary treatment and disinfection upgrades. The NPDES permit limited discharges to the Marsh to periods of lower water levels when the Marsh was not hydraulically connected to the Lake. The tertiary treatment upgrades were not completed and the discharge point was never used so the NPDES permit was not renewed when it expired in 2005. In 2005, the Santa Ana Regional Board issued Order No. R8-2005-0044, as discussed in Section 4.2.1, which does not allow discharge to the Marsh. A new NPDES permit would be required for the Lake Alternative to address discharges into the Marsh, the Lake, and the Shay Pond Stickleback habitat.

5.2 STICKLEBACK FISH HABITAT

5.2.1 History

The Unarmored Threespine Stickleback (*Gasterosteus aculeatus williamsoni*), also known as UTS (referred to as "Stickleback" in this study), is listed as both a Federal and State of California Endangered Species under the respective Endangered Species Acts (1). On the California list, the Stickleback is also given the title of Fully Protected Species (2). The Stickleback lives in California and have been on the Federal list since 1970 and on the State list since 1971 (2) (3). There has been a population of Stickleback in the Shay Creek area on the east side of the Valley, as shown in Figure 5-3, which includes Shay Pond, Sugarloaf Pond, Juniper Springs, Motorcycle Pond, Shay Creek, Wiebe Pond, and Baldwin Lake (10). By the summer of 1990, it was thought that the Stickleback remained in only Shay Pond; however, several years of above-average precipitation in the mid-1990s resulted in the establishment of a pool of water in Baldwin Lake (10). This study focusses primarily on Stickleback in Shay Pond.

There is a long history of study and group effort regarding the Stickleback in the Shay Creek area. The main stakeholders include the United States Fish and Wildlife Service (USFWS), California Department of Fish and Wildlife (CDFW), the San Bernardino National Forest (SBNF), BBCCSD, BBLDWP, and BBARWA. Additionally, the Shay Creek Working Group, which includes representatives from the USFWS, CDFW, SBNF, BBCCSD, DWP, and BBARWA, was formed during the process of preparing the USFWS' 2002 Biological Opinion (BO) for the area (4).

The Shay Creek Working Group has been meeting since 1999 to address and resolve issues related to the Stickleback in the Shay Creek area, including re-initiation of Section 7 consultation resulting in a 2007 Draft revised BO (1). The 2007 Draft BO has not been finalized so the 2002 BO is still in effect. The primary issue that requires resolution is the impact on the Stickleback habitat from three Special Use Permits issued by the SBNF to BBCCSD (for groundwater extraction and spring diversion), BBLDWP (for groundwater extraction), and BBARWA (for wastewater effluent outfall line) (1). Studies and discussions indicate that the actions these permits allow may be adversely impacting the Stickleback in Shay Creek (4).

In 2009, the USFWS conducted a 5-Year Review Summary and Evaluation of the Stickleback, which stated that the Stickleback spend all of their life in freshwater and the ideal habitat for Stickleback is a small, clean pond in the stream with a constant flow of water through it. The Stickleback tend to gather in areas of slower-moving or standing water (10 p. 12).

One of the Conservation Measures for the Stickleback in the Description of the Proposed Action in the 2002 BO is "Shay Pond Land Acquisition", which includes acquisition of the land on which Shay Pond lies, as well as some additional area immediately around the pond to adequately maintain and manage the aquatic habitat(4 p. 4). This has been completed with involvement from BBCCSD, DWP, and BBARWA (5).

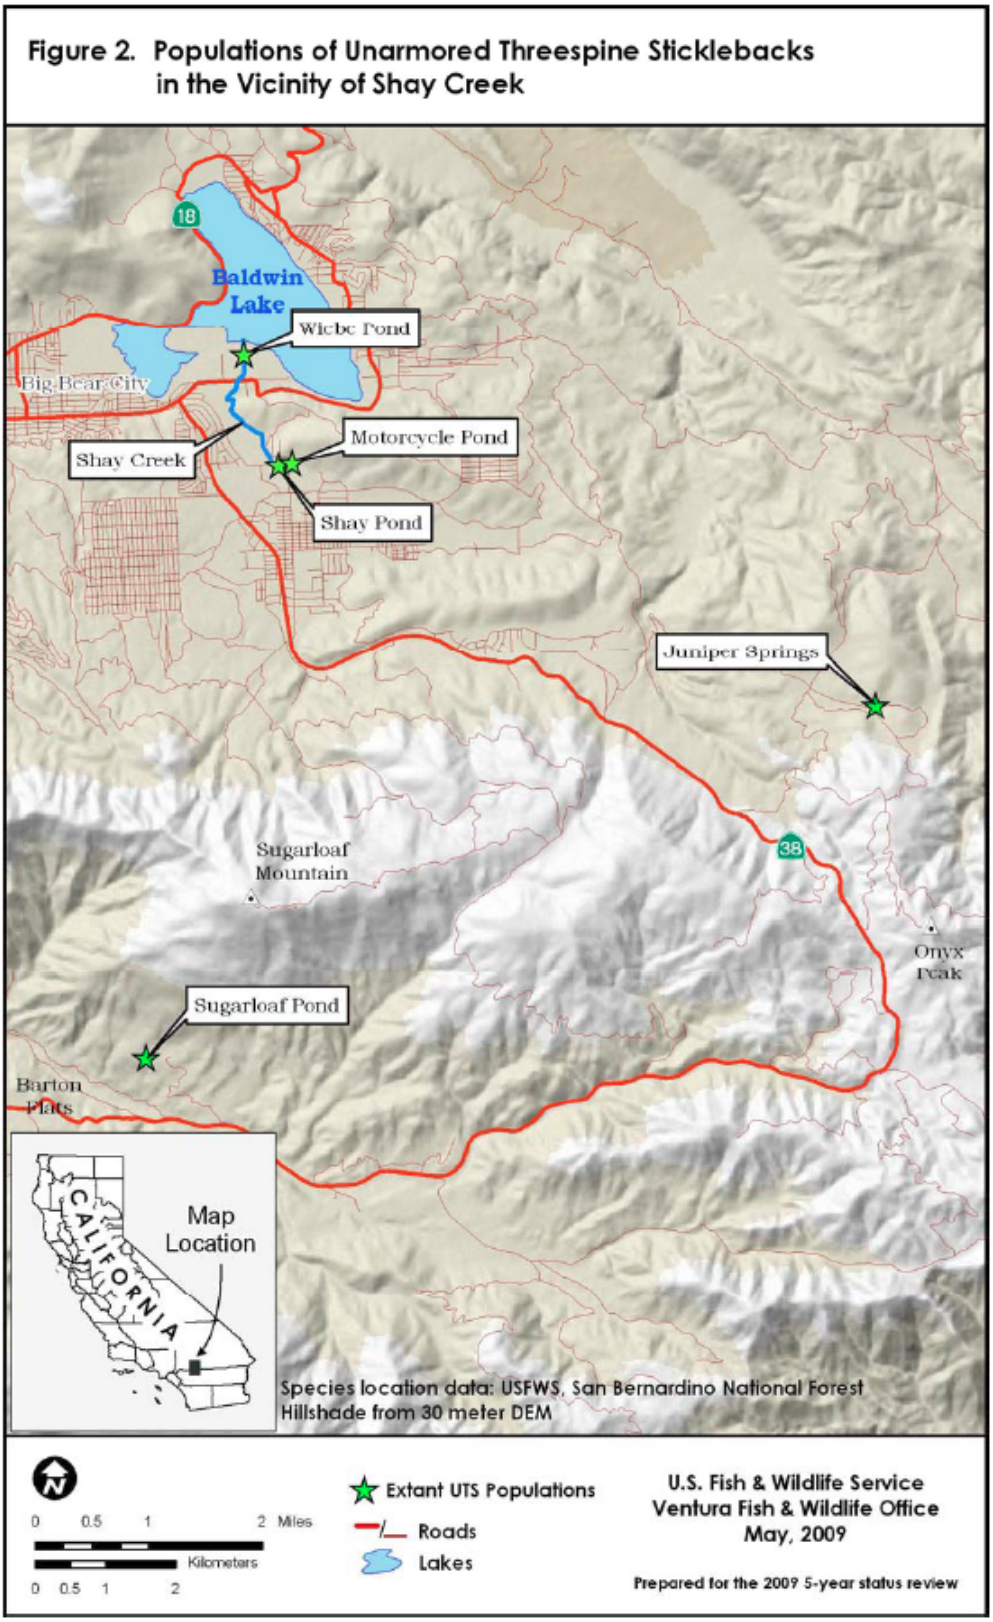

Figure 5-3. Populations of Stickleback in the Shay Creek Area (3 p. 11)

Per the 5-Year Review, there are habitat threats that are specific to the Shay Creek area, including wetland vegetation growth and encroachment, pollution or eutrophication from contamination from horse manure, and loss of flow in the creek due to property development in the area (3 p. 20). To mitigate wetland vegetation growth and encroachment, Shay Pond was dredged by BBCCSD in 2011 (5), and again most recently in 2017. Figure 5-4 and Figure 5-5 show the pond before and after the 2011 dredging, respectively.

Figure 5-4. Shay Pond Before Dredging (5)

Figure 5-5. Shay Pond After Dredging (5)

5.2.2 Shay Pond Water Supply

The requirements of the 2002 BO state that BBCCSD will continue to provide water to Shay Pond to maintain a minimum 20-gallon-per-minute outflow from Shay Pond. To meet this outflow requirement, BBCCSD discharges 50 gpm of potable water into the pond. This equates to 80 AFY, which is significant for BBCCSD because it represents approximately 9% of BBCCSD's customer water demand. The objective is to maintain a minimum pond water level that will support suitable habitat conditions for the fish. BBCCSD currently meets this requirement by discharging potable water into Shay Pond, but the 2002 BO also states that, should a suitable alternative supply of water be found to be appropriate for the stickleback in the future, BBCCSD may use an 'in-lieu' water supply, which could include the use of tertiary-treated water. Prior to use as an in-lieu supply, tertiary-treated water must be studied to confirm suitability to support long-term Stickleback survival, see Section 4.1.3.1 for details. The Lake Alternative would provide an in-lieu water supply for Shay Pond to meet the requirements of the 2002 BO, which would enable BBCCSD to recover this potable supply to serve their customers.

5.2.3 Next Steps for Implementation

Implementation of the Lake Alternative will require further investigation into the suitability of the proposed recycled water quality for discharge into Shay Pond. The concept of providing recycled water to Shay Pond has been evaluated by BBARWA previously. In the Mitigation Monitoring and Reporting Program (MMRP) of the *Final Program Environmental Impact Report for the Big Bear Area Regional Wastewater Agency's Recycled Water Master Plan* (Final EIR), Biological Resources Mitigation Measure 4.5-8 states that: "BBARWA shall initiate a long-term study of Stickleback survival in recycled water if this component of the [Recycled Water Master Plan] program is implemented. The following steps will be implemented: (1) obtain submittals outlining a proposed study program to answer the question of whether the Stickleback can survive and breed over several generations without any measurable damage to individuals or the population; (2) consult with the [USFWS] and [CDFW] to obtain concurrence and approval to implement the study program; (3) fund the study implementation and compile a report of results and recommendations; and (4) submit the report and recommendation to the [USFWS] and [CDFW] with the objective of obtaining an incidental take permit to use recycled water to supplement the habitat in Shay Creek and replace potable water currently being used for this purpose," (6 p. 12). Specific issues that are anticipated to be addressed through these studies include contaminants of emerging concern (CECs), endocrine disrupting compounds (EDCs), and temperature.

Another parallel path could include seeking outside partnerships to develop and implement this beneficial use alternative. For instance, in the late 1990s, the National Heritage Foundation (NHF) sought a partnership with BBARWA to upgrade the WWTP to tertiary treatment to provide water for creation of a new Stickleback habitat in Baldwin Lake. The NHF obtained grant funding to support the construction of treatment upgrades and the pipeline to the new habitat, although this work was not ultimately completed. Additionally, The Nature Conservancy (TNC) played a role in developing a plan in the Santa Clara River watershed addressing important Stickleback habitat (3). The Project Team could coordinate with the NHF, TNC, and/or other similar organizations focused on habitat restoration to evaluate partnership opportunities to further study and enhance the Stickleback habitat.

A new NPDES permit would be required for the proposed discharge into Shay Pond.

5.3 GROUNDWATER RECHARGE AT SAND CANYON

Groundwater recharge at Sand Canyon was evaluated by Thomas Harder & Co. (Harder) to assess the feasibility of recharging the groundwater aquifer at Sand Canyon using surface water from Big Bear Lake and estimate the annual recharge capacity. Harder found that the recharge potential at Sand Canyon is approximately 380 AFY over a 6-month period, based on a recharge area of approximately 4.2 acres and a recharge rate of 2.1 ft/day. The primary limit to recharge rates in the Sand Canyon area appears to be available subsurface storage space to accommodate the groundwater mound. The target maximum groundwater level relative to the land surface was 20 ft below ground surface because previous studies in the Big Bear area have shown that this depth is protective of liquefaction. The full technical memorandum presenting Harder's analysis is attached as Appendix A.

The Sand Canyon recharge concept involves extracting water from the Lake (a blend of surface water and recycled water) and discharging it into Sand Canyon, which serves as a flood control channel. The recharge operation would only occur during dry periods when needed to supplement groundwater supply and would be operated intermittently as needed to avoid interference with flood flows. Prior studies evaluating potential recharge operations in Sand Canyon considered constructing a series of small berms along the streambed to create a percolation area or modifying stream channel to create a meandering stream with small natural ponds to slow the water down and enhance percolation. An additional concept that could be considered is the use of inflatable rubber dams in the channel which could be inflated to create percolation ponds during the recharge operation only and deflated at all other times so as not to impact the natural function of the channel. All of these concepts would need to be coordinated with the flood control agency to ensure that the capacity of the flood control channel remains sufficient to meet the primary purpose of providing flood protection. If these improvements resulted in a decrease in surface flow entering the Lake, the impact to surface water rights under the 1977 Judgment would need to be evaluated.

When water is needed for recharge in Sand Canyon during dry periods, it is assumed that the existing lake pump station owned by Big Bear Mountain Resort (Ski Resort) could be used to transfer water through an existing pipeline into the existing storage pond located at Bear Mountain Ski Resort. These facilities are used primarily for snow making in the winter and are expected to be available for the proposed recharge operation, which would only occur in April – October when the resorts are not making snow. The Project Team has conducted preliminary discussions with the Resort about the Lake Alternative and potential joint use of their snowmaking facilities. The Resort is interested in the Lake Alternative because low Lake levels significantly complicate their snow making operation so they would benefit from an increase in Lake levels. The Project Team will continue discussions with the Resort and work to develop a mutually agreeable arrangement for joint use of the snowmaking facilities. This study assumes joint use of the snowmaking facilities will be viable and that a new pump station would be constructed near the Resort pond to convey water through a new pipeline to discharge into Sand Canyon, as shown in Figure 7-3. If a joint use arrangement for the snowmaking facilities cannot be negotiated, constructing new pumping and conveyance facilities to reach Sand Canyon would substantially increase the project cost.

5.4 SNOW STORAGE

During wet periods, excess water could be stored as snow at the Resorts using their existing snowmaking infrastructure. This would reduce spills from the Lake, keep more of the water in the Valley and enhance winter recreation by providing additional snowmaking water to the Resorts beyond their current allotment from the Lake. When the snow melts in the spring, runoff would be augmented, which is expected to increase natural groundwater recharge and may improve fish spawning habitat in streams tributary to the Lake. A hydrologic analysis would be required to assess the potential benefits of this component, but this is a flexible strategy to enable to Project Team to further expand the benefits of the Lake Alternative.

Title 22 provides that disinfected tertiary recycled water may be used for artificial snowmaking for commercial outdoor use.

5.5 GOLF COURSE IRRIGATION

As another potential option to keep additional water in the Valley, the existing snowmaking facilities could also be used to deliver irrigation water to the Bear Mountain Golf Course (also owned by the Ski Resort) in the summer, if desired. The water demand for the Bear Mountain Golf Course is estimated to be 120 AFY (1). This option would allow the Resort to rest their groundwater irrigation wells and reduce pumping from the Basin.

Title 22 provides that disinfected tertiary recycled water may be used for irrigation of unrestricted access golf courses, subject to the restriction that irrigation shall not take place within 50 feet of an unshielded domestic water supply well and that recycled water impoundment may not occur within 100 feet of a domestic water supply well. Additionally, some adjustments to irrigation practices may be needed to comply with the use site requirements in Title 22. This option would need to be coordinated with the Resort.

5.6 DOWNSTREAM RECHARGE

Additional inflows into the Lake will provide BBMWD with more flexibility in managing Lake releases, while still maintaining higher Lake levels than are possible without the Lake Alternative. In particular, during wet periods, additional flood control releases are anticipated that will flow down the Santa Ana River to the Seven Oaks Dam, which is upstream of the San Bernardino Groundwater Basin area. BBMWD intends to coordinate with Valley District in an effort to optimize the volume of releases from the Lake that can be captured for recharge of the San Bernardino Basin, rather than flow past to the ocean. A Seven Oaks Dam capture project is underway that will enable Valley District to vastly increase their capacity to recharge water released from the Seven Oaks Dam. To further assess the potential benefits to recharge in the San Bernardino Basin, a hydrology study is needed to estimate the volume and timing of additional flows under a range of hydrologic conditions. That information can then be input into Valley District's model to assess their ability to capture these flows for recharge.

6 TREATMENT UPGRADE REQUIREMENTS

A key consideration in the development of any recycled water project is the required quality and treatment level of the recycled water as established by various permitting agencies and State Regulations. The key drivers for treatment upgrades for the Lake Alternative are described in this section.

6.1 BASIN PLAN WATER QUALITY OBJECTIVES

In order to recharge the Basin or discharge recycled water to the Lake, the recycled water must meet the water quality objectives set by the Santa Ana River Basin Water Quality Control Plan (Basin Plan). The Basin Plan establishes beneficial uses and water quality objectives (WQO) for the ground and surface waters of the region and includes an implementation plan describing the actions by the RWQCB and others that are necessary to achieve and protect the water quality standards. The Basin Plan provides a general narrative regarding the WQO for each water body type and specific numeric objectives for total dissolved solids (TDS), hardness, sodium, chloride, total inorganic nitrogen (TIN), total phosphorus (TP), sulfate, and chemical oxygen demand (COD). Additional information about the Basin plan is provided in Appendix B of the 2016 Study. The WQO for the Big Bear Valley are summarized in **Table 6-1**. As shown, the WQOs for Big Bear Lake are the most stringent of the proposed discharge points and will therefore govern the treatment upgrades required for the Lake Alternative.

Table 6-1. Basin Plan Water Quality Objectives

Water Body	TDS	Hardness	Sodium	Chloride	TIN	Sulfate	COD
Inland Surface Streams							
Rathbone Creek (downstream of Sand Canyon)	300	-	-	-	-	-	-
Shay Creek (Narrative Objectives)	-	-	-	-	-	-	-
Lakes and Reservoirs							
Big Bear Lake	175	125	20	10	0.15	10	-
Wetlands (Inland)							
Stanfield Marsh (Narrative Objectives)	-	-	-	-	-	-	-
Groundwater Management Zones							
Big Bear Valley	300	225	20	10	5	20	-

6.1.1 Big Bear Lake Nutrient Limits

In addition to the numeric and narrative WQOs, Big Bear Lake is subject to a Total Maximum Daily Load (TMDL) numeric target of 35 µg/L-P for total phosphorus during dry hydrologic conditions, per Resolution No. R8-2006-0023. By 2020, the total phosphorus numeric target must be achieved at all times. A causal target was established for phosphorus because it was determined to be the limiting nutrient in the lake; however, nitrogen may be the limiting nutrient under certain conditions and as a result, a nitrogen TMDL may be established in the future. Data collected in accordance with the Big Bear Lake Watershed-wide Nutrient Monitoring Plan is currently used to assess compliance with the lake's water quality objectives, and can also assist in determining nutrient TMDL waste-load allocations (WLAs) and numeric targets for nitrogen in the future. Response targets for macrophyte coverage, percentage of nuisance aquatic-vascular plant species and chlorophyll a concentration have also been implemented under the nutrient TMDL to further assess water quality improvements in the lake.

The nutrient limits for an NPDES permit to Big Bear Lake are expected to align with the Basin Plan WQOs and the TMDL numeric targets to protect the beneficial uses of the lake. The anticipated effluent nutrient limits of 35 µg/L-P for total phosphorus and 0.15 mg/L-N for total inorganic nitrogen would require multiple process steps and consistent treatment through seasonality. For a cold climate like Big Bear's, compliance with stringent nutrient limits through the winter season would be the greatest challenge due to decreased biological nutrient removal when wastewater temperatures drop below 10-degrees Celsius. Some California wastewater facilities that operate in cold climates have separate summer and winter nutrient limits in consideration of this seasonal affect – the winter limits being less stringent – although it is unknown at this point if BBARWA's future discharge permit would be considered for seasonal limits. The treatment required to meet the expected phosphorus and nitrogen limits includes enhanced nutrient removal processes and technologies, as further described in Section 7.1 of the report.

Note that the RWQCB may consider permitting increased nutrient limits for the discharge if an approved nutrient offset program is implemented as well. A nutrient offset program would reduce nutrient loads elsewhere in the watershed by an amount at least equal to the amount discharged in excess of the WQO. Coordination with the RWQCB staff is needed to explore potential opportunities for a nutrient offset program in the Valley.

6.2 SURFACE WATER DISCHARGE

Based on initial discussions with the SWRCB Division of Drinking Water (DDW), this project would not likely be considered a Surface Water Augmentation project because the Lake is not used directly as a drinking water source and the environmental buffer between the discharge point and downstream uses is extremely large. Additional coordination with DDW is needed to verify the permitting strategy and technical analysis may be required to support DDW's determination.

6.3 GROUNDWATER RECHARGE REQUIREMENTS

Several key regulatory requirements for groundwater recharge are described in the following subsections.

6.3.1 Recycled Water Concentration

The groundwater replenishment regulations in Title 22 require that the initial concentration of filtered and disinfected tertiary recycled water (Recycled Water Concentration or RWC) not exceed 20% of the total recharge water, which requires 80% of the total recharge water to come from other high-quality water sources for blending. Blend water can be a combination of imported SWP water, captured surface water, or natural underflow. If sufficient dilution water is not available from these sources, advanced purified recycled water using reverse osmosis (RO) and advanced oxidation can serve as a dilution source. As discussed previously, SWP water is not available in the Valley. The Groundwater Recharge Regulations assess a project's compliance with the RWC requirement using a 120-month running monthly average.

The Lake Alternative proposes to discharge treated water to the Marsh, which will flow through to the Lake and blend with surface water captured in the Lake, which is expected to be a qualified dilution water source. Based on annual Lake inflows from 1977 to 2016 (5), the lowest 10-year rolling average of Lake inflows over this period was 10,389 AF, which occurred in 2016. Based on effluent flows from 2007-2016, the anticipated 10-year average recycled water flow into the Lake is approximately 1,950 AF, which would equate to approximately 16% RWC in the Lake on a 10-year rolling average.

In addition, natural underflow beneath the Sand Canyon recharge area is expected to qualify as a dilution source. A preliminary estimate of underflow volume was developed by Thomas Harder & Co. in the Sand Canyon Recharge Evaluation Technical Memorandum, dated November 29, 2017 and attached as Appendix A. Depending on the interpretation of the data by the SWRCB Department of Drinking Water (DDW), the underflow dilution credit is estimated to range from 58 AFY to 247 AFY, which would further reduce the RWC of 16% from the blended Lake water. Based on this preliminary assessment of available diluent water, groundwater recharge at Sand Canyon with blended water from the Lake is expected to meet the initial RWC requirement of 20%.

Because the Lake WQO are much more stringent than the Basin WQO, it is anticipated that the blended water from the Lake will meet the WQOs for groundwater recharge in the Basin.

At the planning level, there is some uncertainty in the treatment requirements because the qualifying dilution water has not been fully quantified. If needed, project proponents have an opportunity to perform additional analysis to demonstrate to the RWQCB and DDW that tertiary treatment and dilution water will meet the Title 22 and Basin Plan requirements. The RWQCB and DDW will make the final decisions on the required treatment levels after review and evaluation of technical information presented by the project proponent during the permitting process.

6.3.2 Minimum Travel Time

The Groundwater Recharge Regulations require a minimum "response retention time" or minimum groundwater travel time of two months between the point of surface application or injection, and the point of extraction. Harder's preliminary analysis shows that the recharge water will reach the nearest production well (Sheephorn Well) in a little more than approximately 13 months. For preliminary recharge siting purposes, the Groundwater Recharge Regulations allow a "credit" of 0.25 for travel time calculations using an analytical model, as was done for this analysis. Thus, the credited retention time is interpreted to be 3.25 months (13 x 0.25). This credited retention time is less than the minimum retention time of 2 months, indicating that the simulated recharge operation is feasible based on the data assumptions in the analysis.

6.3.3 Pathogen Control

Pathogen controls include specific provisions for log reduction of microorganisms and treatment process requirements. The treatment process used to treat recharge water for a GRRP must provide treatment that achieves at least 12-log enteric virus reduction, 10-log Giardia cyst reduction, and 10-log Cryptosporidium oocyst reduction from raw sewage to usable groundwater. The treatment train shall consist of at least three separate treatment processes. For each pathogen (i.e., virus, Giardia cyst, or Cryptosporidium oocyst), a separate treatment process may be credited with no more than 6-log reduction, with at least three processes each being credited with no less than 1.0-log reduction. If the treatment process itself does not achieve the required pathogen control credits, additional credit can be gained through underground retention time prior to extraction. The pathogen control credit requirement and underground retention time should be considered as part of the treatment process selection during preliminary design.

7 LAKE ALTERNATIVE ANALYSIS

The following subsections provide additional information about the Lake Alternative, including treatment upgrades, yield, brine disposal alternatives, treated water distribution, and a summary of capital and operating costs.

7.1 TREATMENT UPGRADES

For the Lake Alternative, BBARWA's existing wastewater facility will be upgraded to meet the water quality objectives identified for Big Bear Lake in the Santa Ana Basin Plan (Table 6-1). Inorganic nitrogen and phosphorus must be removed through multiple in-series processes because a single process cannot reliably reduce effluent TIN and TP concentrations to the levels required for Big Bear Lake's WQOs. To achieve these strict effluent limits, it is anticipated that BBARWA will need to implement a series of upgrades to existing unit processes and integrate new unit processes, specifically:

- Upgrade the extended aeration process through retrofit of the existing oxidation ditches to optimize biological nitrification-denitrification (NDN) and phosphorus removal. Phosphorus removal occurs in anaerobic conditions and denitrification occurs in anoxic conditions, both of which could be incorporated into the existing infrastructure with modifications to aeration patterns or with dedicated tanks. If needed, chemical precipitation of soluble phosphorus can be performed through addition of a metal salt within the activated sludge tankage, upstream of clarification.
- Nutrient-laden liquid sidestreams, which are produced during solids handling processes, may require management or treatment due to the potential negative impacts of returning high nutrient loads to other unit processes. The need for sidestream treatment will be determined during subsequent phases of the project when a plant-wide mass balance and/or process model can be developed to identify sidestream characteristics.
- Retrofit or operational modifications to secondary clarifiers for settling of phosphorus precipitates. It is important to note that chemical precipitation of phosphorus within the existing clarifiers requires an evaluation of effects on sludge production and handling. Removal of phosphorus through chemical precipitation is expected to increase solids production and impact operation of the current solids handling process.
- Addition of an NDN process to reduce inorganic nitrogen concentrations. This process may consist of a biologically active filter with sand or synthetic media, or biological reactors designed specifically for nitrogen and phosphorus removal. The denitrification process will likely require an external carbon source to facilitate the reduction of nitrate.
- Low pressure filtration, such as microfiltration (MF) or ultrafiltration (UF), to reduce flocculated or colloidal solids upstream of the reverse osmosis (RO) process.

- RO to reduce TDS concentration and nutrient concentrations. The assumed operational recovery for the RO system is 90% of the design flow. While it may be challenging for conventional RO systems to achieve this recovery rate, emerging RO technologies that are configured for brine recirculation, multiple pass, or in-series operation to achieve high recoveries (such as closed-circuit reverse osmosis), have been demonstrated to achieve high recovery rates with reduced energy consumption at comparable capital costs to conventional RO (15). Such technologies would need to be piloted with BBARWA's specific water quality characteristics to verify expected performance for this application.

  The low-pressure filtration and RO unit processes are expected to provide the physical filtration for reduction of the 1 to 2 mg/L of TIN and TP coming from upstream processes. RO is the only unit process capable of removing TDS, making it a critical unit process for compliance with WQOs. It is assumed that 100% of the design flow will need to receive RO treatment to meet the WQOs. RO offers the advantage of removing organics, inorganics and nutrients to a sufficient level for meeting nutrient WQOs; however, the RO process also presents the challenge of managing brine stream disposal in an inland location, as further discussed in Section 7.3.

A representative process flow diagram (PFD) for this alternative is shown in Figure 7-1. Potential water quality performance for TIN, TP and TDS constituents are estimated for each unit process; however, it is important to note that the performance of each of these unit processes is highly site specific based on the water quality composition being treated. A pilot test of each unit process is recommended to refine performance estimates and establish design criteria.

		Primary Treatment	Enhanced Nutrient Removal	Nitrification-Denitrification Process	Low-Pressure Filtration	Reverse Osmosis
Potential Water Quality Performance	TIN (mg/L-N)	--	5	1	1	0.1
	TP (mg/L-P)	8	2	2	0.1	0.02
	TDS (mg/L)	430	430	430	430	50*

Figure 7-1. Representative Treatment Process Flow Diagram for the Lake Alternative

7.1.1 Effluent Temperature

It should be noted that Lake water temperatures and WWTP effluent temperatures vary seasonally. While they are relatively similar in the summer months, the WWTP effluent temperature is considerably higher than the Lake temperature in the winter, as shown in Figure 7-2. It is expected that the discharge permit for this alternative would include limits for effluent temperature, and/or the allowable temperature change in the Lake caused by the discharge to avoid adverse thermal impacts to aquatic habitat. As a result, the treatment upgrades may need to include a provision for effluent cooling during winter.

Temperature reduction of the effluent may be achieved through a variety of methods or a combination of methods (16). Potential methods that may be applicable to BBARWA's WWTP include:

- Selecting a disinfection process with lower relative heat addition than other alternatives (i.e. chlorine contactor or UV) and by covering the disinfection facility to reduce solar energy addition
- Use of a multiple port diffuser system at the discharge location to facilitate more rapid mixing with the receiving water
- Discharge into a constructed wetland with long detention times through shaded, deep narrow channels
- Discharge into shallow reservoir to act as a cooling pond to achieve evaporative and radiative heat loss prior to surface water discharge. Depending on the configuration of the treatment process, the existing secondary effluent storage ponds may be able to provide some cooling benefit
- Spray cooling, which uses evaporative cooling to remove heat from treated wastewater by spraying it into the air from a lined pond when the ambient temperature is significantly lower than the effluent temperature. Spray cooling could potentially be implemented in the secondary effluent storage ponds and would require the installation of a pump, manifold and nozzles.
- Cooling towers or chillers could be considered, although they are expensive to install and operate so this equipment is not desirable

The need for effluent cooling should be assessed during the preliminary engineering phase once discharge temperature criteria are more well defined. The costs for the Lake Alternative presented in Table 7-5 do not include the cost of effluent cooling, if required.

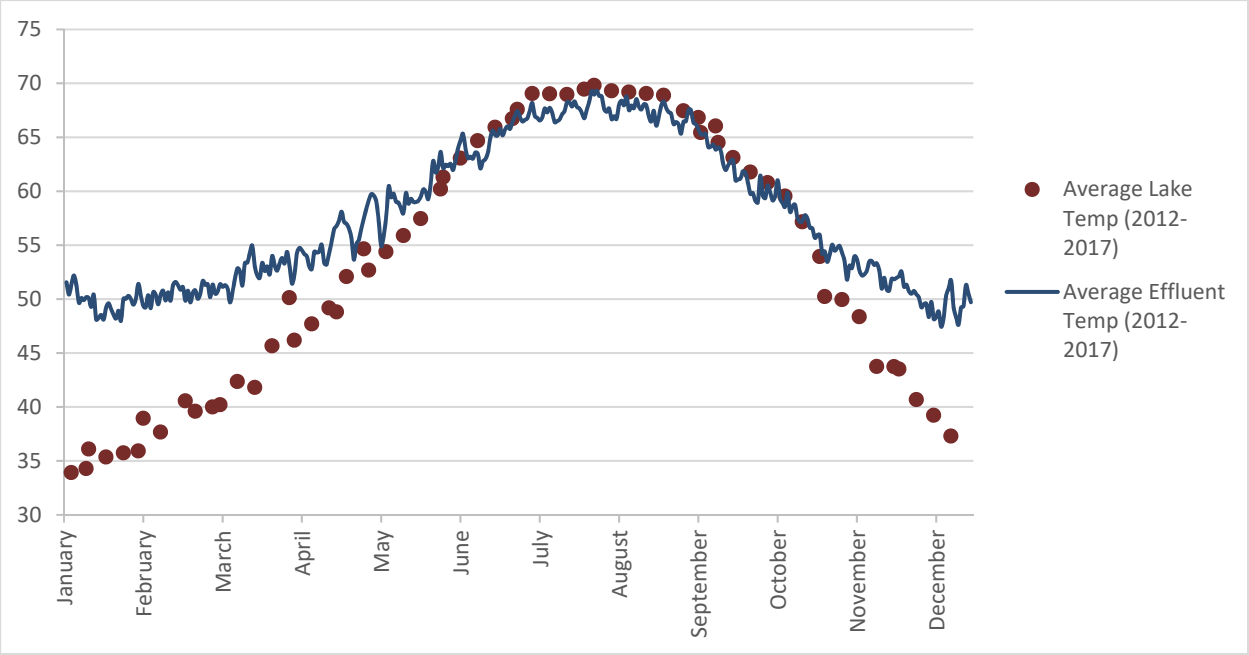

Figure 7-2. Comparison of Average Lake and BBARWA Effluent Temperatures (2012-2017)

7.2 DESIGN CAPACITY AND ANNUAL YIELD

The design capacity of the treatment upgrades is assumed to be 2.2 mgd, which corresponds with the 10-year average annual flow. Based on a preliminary sizing analysis, increased treatment capacity results in only a marginal increase in yield and does not provide an appreciable increase in economic or environmental benefit. It is assumed that any flows in excess of 2.2 mgd would be treated to a secondary level and discharged to Lucerne Valley, similar to the existing discharge method.

However, due to daily and seasonal variations in flow, the actual yield will be less than 2.2 mgd. It is assumed that the secondary effluent storage volume will offset some daily variations in flow, but the capacity is not sufficient to offset seasonal variations, particularly in dry years when summer flows have been as low as 1.6 mgd. A preliminary analysis based on monthly flows for the 10-year period from 2007-2016 indicates that the average secondary effluent available will be approximately 1.93 mgd, or 2,160 AF. Based on a 90% recovery rate, the average recycled water production would be 1.74 mgd, or approximately 1,950 AFY.

Note that recycled water production may increase in the future as average dry weather flows increase due to growth; however, continued conservation may offset some increases. Additionally, reduced design capacities could be evaluated to determine the optimal cost to yield ratio. It is recommended that the design capacity and RW production estimates be refined during the preliminary and final design phases based on more detailed flow data and actual MF and RO recovery rates.

7.3 BRINE DISPOSAL - SOLAR EVAPORATION PONDS

A key challenge with implementation of RO treatment, particularly in inland communities, is effective management of the brine concentrate. The most common brine concentrate disposal options include deep well injection (where permitted), surface water discharge (including the ocean), discharge to a wastewater treatment plant (such as via the Inland Empire Brine Line), land disposal, and solar evaporation or Zero Liquid Discharge (ZLD) with disposal of solids to a landfill. Deep well injection, surface water discharge, and land application are not feasible due to regulatory and geologic constraints (14). Discharge to the Inland Empire Brine Line is assumed to be infeasible because the nearest discharge point is over 20 miles away in straight line distance and the capacity is fully subscribed. ZLD, a combined evaporation and crystallization process that produces a dry waste, has relatively high capital and O&M costs and operational complexity compared to other disposal alternatives, and is typically only considered for disposal of municipal brine when no other disposal option is available (17). Therefore, ZLD is not evaluated in this study.

The focus of this section is a preliminary evaluation of several solar evaporation pond alternatives. Evaporation ponds rely on solar energy to evaporate water from the brine concentrate stream, leaving behind precipitated salts, which ultimately are disposed of in a landfill. Evaporation ponds for brine concentrate disposal are most appropriate for smaller volume flows and for regions having a relatively warm, dry climate with high evaporation rates, level terrain, and low land costs. Evaporation ponds are relatively easy to construct, are low maintenance and have no mechanical equipment except for pumps to convey brine to the ponds. However, pond size requirements can be quite high depending on the brine flow and evaporation rates and the regulatory requirement for impervious liners of clay or synthetic membranes substantially increases the cost of construction. Monitoring wells will be required to verify that seepage from the ponds is not contaminating underlying groundwater.

A comparative analysis of evaporation ponds located in either the Big Bear Valley on the WWTP site or in the Lucerne Valley on BBARWA's 480-acre site is presented in this section.

7.3.1 Brine Volume & Reduction

As discussed in Section 7.2, the actual treated flow may be lower than the design capacity of 2.2 mgd; however, the full capacity of 2.2 mgd is used for this brine disposal analysis to ensure sufficient disposal capacity if higher recovery rates area achieved or flows increase in the future due to growth.

As discussed in Section 7.1, the estimated recovery of the RO process is 90%, so 10% of the treated flow, or 220,000 gallons per day (gpd), will be brine concentrate. If recovery of additional water is desired or if it is necessary to reduce the size of the evaporation pond, an additional treatment process can be added to further concentrate the brine volume. Potential brine concentration processes include electrodialysis reversal (EDR), Vibratory Shear Enhanced Process (VSEP) and Enhanced Membrane Systems (EMS), which were previously evaluated for BBARWA (14). Although these processes recover additional water for beneficial use, they are relatively high in capital and O&M cost and increase operational complexity.

For the purposes of this analysis, a brine concentrator is assumed to have a 90% recovery rate, so 10% of the original brine concentrate, or 22,000 gpd, will be discharged to an evaporation pond. Brine concentrator recovery rates greater than 90% may be achievable and would further reduce the brine volume discharged to the evaporation pond. The water recovered from a brine concentrator is expected to be relatively low in TDS (less than 500 mg/l), so it expected that the product water could be blended with the RO permeate and still meet the TDS WQO for the proposed uses.

7.3.2 Evaporation Rates and Pond Size

Due to a higher evaporation rate and lower precipitation, ponds located in Lucerne Valley could be smaller than ponds located in Big Bear Valley. The estimated evaporation rate in Lucerne Valley is 63 inches per year (14) and average annual precipitation is 8.4 inches per year (15). The estimated evaporation rate in the Big Bear Valley is 45 inches/year (14) and the average annual precipitation at the BBCCSD station is 14.4 inches per year (5). Although the average annual evaporation rate calculated for the Lake in the Big Bear Watermaster Annual Reports is higher at 51.2 inches per year (previous 12-year average), the lower value of 45 inches per year is used in this comparative analysis to be consistent with the evaporation data available for the Lucerne Valley region.

Evaporation efficiency of brine is significantly lower than fresh water; while complex site-specific variables impact the actual evaporation rate, an evaporation ratio of 0.70 is considered a reasonable allowance in absence of site specific data (16). Subtracting the annual precipitation from the annual evaporation and adjusting for brine evaporation efficiency yields a net evaporation rate of 38.2 inches per year in Lucerne Valley and 21.4 inches per year in Big Bear Valley.

The required evaporative area of an evaporation pond is based on the flow rate of brine and the evaporation rate but the actual pond area constructed should be at least 20% larger to allow for operational contingency and space for dikes and service roads (16). Total evaporation pond areas for the two location and brine volume options were calculated using an evaporation pond regression model (17) and are presented in Table 7-1.

Table 7-1. Evaporation Pond Areas

	Evaporation Pond Total Area, acres	
Brine Flow Rate	**Big Bear Valley**	**Lucerne Valley**
RO Concentrate (220,000 gpd)	138	78
Reduced Brine (22,000 gpd)	13.8	7.7

As shown, the evaporation pond areas are greatly reduced when the brine is concentrated; however, brine concentrators add a significant capital and O&M cost that may offset the cost savings and benefits of the reduced pond size. The BBARWA WWTP site is 80 acres and the adjacent land is primarily in the flood plain and/or National Forest System Land so a 138-acre evaporation pond near the WWTP site in Big Bear Valley is not likely feasible.

7.3.3 Brine Storage and Conveyance

7.3.3.1 Big Bear Valley

If the evaporation ponds are located at the BBARWA WWTP site, the brine is assumed to be conveyed directly from the treatment process to the evaporation ponds so brine storage and brine pumps would not be required. A new pipeline from the RO process to the evaporation ponds would be needed. An allowance of 2,000 feet is included in this analysis, assuming that the evaporation ponds are located within the current WWTP site.

7.3.3.2 Lucerne Valley

If evaporation ponds are located in the Lucerne Valley, BBARWA desires to use the existing effluent pipeline for brine conveyance as it is not financially feasible to construct a second pipeline to Lucerne Valley. Because this pipeline will also need to be used to convey peak flows to the Lucerne Valley site, the operational strategy to maintain dual use of this pipeline will be an important consideration to ensure that BBARWA is able to remain in compliance with discharge permit requirements at all times.

The key constraint on the use of the pipeline is anticipated to occur during winter periods with sustained higher flows. During these periods, the availability of the pipeline to convey brine to Lucerne Valley will be limited and brine discharges will need to occur in a series of relatively short windows during which the effluent storage provides a buffer to discharge brine. The maximum month effluent flow from the WWTP in the 10-year period from 2007-2016 occurred in March 2011 and was 169 million gallons (MG), or an average monthly flow of 5.6 mgd. The maximum daily flow in March 2011 was 7.6 mgd, but the maximum day flow in the 10-year period was 9.6 mgd on December 22, 2010, which is equal to the maximum capacity of the effluent pump station. The WWTP has 10 MG of emergency storage that provides sufficient capacity to manage peak hour flows (18) so 9.6 mgd is the maximum expected effluent flow, limited by the capacity of the auxiliary effluent pump station.

The design capacity of the proposed tertiary treatment upgrades is 2.2 mgd, so the secondary effluent discharged to Lucerne Valley will be reduced by that amount during high flow periods. The WWTP has 2 secondary effluent storage ponds with a combined storage of 5 MG. Table 7-2 shows the duration of time that the effluent pumps can be turned off during peak flow periods and the duration of time they will need to run to empty the storage ponds once they are filled. At a minimum, 13 hours of brine storage volume must be provided at the WWTP to allow for the secondary effluent pumps to empty the ponds. During a peak day event, the secondary effluent storage will refill in only 15 hours so additional brine storage is recommended to provide operational flexibility so that operators do not have to transition from effluent to brine discharge during a peak day while also managing peak hour flows using the emergency storage pond. For this analysis, 3 days of brine storage is assumed, but this could be increased if additional operational flexibility is needed. The brine pump station is sized to empty the brine storage tank in 35 hours so that it can be emptied within the effluent storage window of the 1-Year max month flow condition in Table 7-2. The resulting brine storage and pumping capacities are shown in Table 7-3.

Table 7-2. Secondary Effluent Storage and Pumping Durations in Peak Flow Periods

Wet Weather Flow Condition	Total Flow, mgd	Secondary Effluent Flow, mgd[1]	Hours of Secondary Effluent Storage[2]	Minimum Time to Empty Secondary Effluent Storage[3]
10-Year Maximum Month Flow (2007-2016)[4]	3.3	1.1	109 hours	13 hours
1-Year Maximum Month Flow (2011)	5.6	3.4	35 hours	13 hours
Peak Daily Wet Weather Flow	9.6	7.6	15 hours	13 hours

Notes:
1. Total Flow minus 2.2 mgd which is diverted to the tertiary treatment system
2. Time to fill 5MG secondary effluent storage when effluent pumps are off, assuming that it is emptied by a prior pumping cycle. This is the available window for brine discharge.
3. Assumes auxiliary pumps are operated at maximum capacity of 9.6 mgd until the ponds are emptied
4. Average of maximum month flows for the 10 year period 2007-2016

Table 7-3. Brine Storage and Pumping Capacity for Lucerne Valley Evaporation Ponds

Brine Flow Rate	Brine Storage Volume, gallons	Brine Pumping Capacity, gpm
RO Concentrate (220,000 gpd)	660,000	470
Reduced Brine (22,000 gpd)	66,000	50

Under this operational scenario, the discharge pipeline to Lucerne Valley would be used for brine discharge for up to 35 hours, then would be available for secondary effluent discharge for up to 3 days while to brine storage tank is refilled. Each time the pipeline use switches from brine to secondary effluent, the brine remaining in the pipeline would need to be flushed into the evaporation pond before the effluent could be applied to the fields. This mode of operation would limit the amount of time the pipeline is filled with brine and may help reduce corrosion potential; however, further evaluation is needed during the preliminary design phase to assess the suitability of the existing cement lined ductile iron pipe to convey brine. A condition assessment and corrosion testing of the pipeline material is recommended to determine whether the existing pipeline would be degraded by this operation. If the pipeline needs to be lined to protect it from corrosion, this would significantly increase the capital cost. A flushing and monitoring protocol would need to be established to ensure that the discharge to the fields remains in compliance with BBARWA's WDR permit which regulates this discharge. The existing WDR permit would need to be modified to include the proposed evaporation pond, subject to approval by the Colorado River RWQCB.

The existing discharge pipeline fills a concrete lined balancing reservoir located approximately 1.25 miles south of BBARWA's LV Site then flows by gravity to the LV site to irrigate the fields. Because the concrete balancing reservoir was not likely constructed with an impervious liner and it would be difficult to flush frequently, it is assumed that brine flows will not enter the balancing reservoir, but be conveyed to the LV site through a new dedicated brine pipeline from the balancing reservoir site, approximately 10,000 feet long. Automatic control valves could be installed at the balancing reservoir site to enable BBARWA to conduct the pipeline flushing remotely before switching to effluent discharge. Note that BBARWA's 2010 Sewer Master Plan indicates that there are 2 parallel pipelines from the balancing reservoir to the LV Site so the configuration and operation of these pipelines should be investigated to evaluate whether one could be repurposed to convey brine to the LV site and eliminate the need to construct a new pipeline.

7.3.4 Brine Disposal Comparative Costs

Comparative capital and O&M costs for each scenario are presented in Table 7-4.

Table 7-4. Brine Concentration and Evaporation Comparative Costs

	Alternative 1	Alternative 2	Alternative 3	Alternative 4
Cost Component[1]	Big Bear Valley RO Concentrate 138 Acre Pond[2]	Big Bear Valley Reduced Brine 13.8 Acre Pond	Lucerne Valley RO Concentrate 78 Acre Pond	Lucerne Valley Reduced Brine 7.7 Acre Pond
Capital Costs				
Evaporation Pond	$13,394,000	$1,339,000	$7,507,000	$750,000
Brine Concentrator	-	$8,522,000	-	$8,522,000
Brine Storage	-	-	$1,432,000	$143,000
Brine Pump Station	-	-	$584,000	$93,000
Brine Pipeline	$290,000	$219,000	$1,837,000	$1,452,000
Total Capital Cost	**$ 13,684,000**	**$ 10,080,000**	**$ 11,360,000**	**$ 10,960,000**
O&M Cost				
Evaporation Pond	$67,000	$7,000	$38,000	$4,000
Brine Concentrator	-	$539,000	-	$539,000
Brine Storage	-	-	$14,000	$1,000
Brine Pump Station	-	-	$52,000	$5,000
Brine Pipeline	$3,000	$2,000	$18,000	$15,000
Total O&M Cost	**$ 70,000**	**$ 548,000**	**$ 122,000**	**$ 564,000**

Notes:

1. Capital costs include 25% markup for construction contingency and 30% markup for implementation. See Appendix B for a summary of capital cost methodology and assumptions.
2. Sufficient space on the existing WWTP site is not available and adjacent lands are primarily in the flood plain and/or National Forest System Lands so this alternative is likely not feasible, or the capital cost will be much higher due to the need for land acquisition.

7.3.5 Representative Evaporation Pond Alternative

As shown in Table 7-4, the capital cost of Alternative 1 is significantly higher than that of Alternatives 2, 3 and 4 and is likely not feasible due to the size of the land required. The remaining alternatives are relatively comparable in capital cost, but the O&M cost of Alternative 3 is substantially lower because it does not include a brine concentrator. Although Alternatives 2 and 4 recover more water for beneficial use due to the additional recovery through the brine concentrator, the unit cost of Alternative 3 is still lower due to the substantially lower O&M costs. Therefore, Alternative 3, which includes disposal of the full RO brine concentrate stream to evaporation ponds at the LV site, is used as the representative brine disposal alternative in this study. If an RO system at the WWTP can achieve greater than 90% recovery, the size of the evaporation ponds can be reduced, which will result in lower costs for all evaporation pond alternatives.

7.4 TREATED WATER STORAGE & DISTRIBUTION

The treated water is planned to be discharged continuously to Shay Pond and Stanfield Marsh; therefore, treated water storage at the WWTP is not included.

A single effluent pump station is assumed to pump purified water to both Shay Pond and Stanfield Marsh; the variation in elevation of the two discharge points is approximately 15 feet. The pump station capacity will match the capacity of the tertiary treatment system, which is 2.2 mgd, or approximately 1,530 gpm. A new effluent pump station is included in the cost estimate in this study, but if the existing effluent auxiliary pumps could be used as the primary secondary effluent pump station, the existing secondary effluent pump station may be able to be repurposed to avoid the need for a new effluent pump station. If this modification is feasible, the cost of effluent pump station improvements could potentially be reduced, but additional evaluation of the existing pump stations and the WWTP operation would be needed to determine if this is a viable option.

There is an existing 6-inch C-900 PVC pipeline that begins at the intersection of Shay Road and Palomino Drive and terminates near Shay pond that can be used to convey purified water to Shay Pond, with an extension of approximately 710 feet to reach Shay Pond. This pipeline was constructed in 1986 for future use, but has never been put into service.

A new 12-inch pipe will need to be installed from the WWTP to the proposed discharge point in Stanfield Marsh, as shown in Figure 7-3. BBARWA identified an existing pipeline that is believed to extend from near the Marsh to the WWTP, however, BBARWA located a valve on this line and found that the number of turns was consistent with a 6-inch pipeline, which is too small to accommodate the proposed flows. Additionally, the year of construction and condition of the pipeline are unknown.

When water is needed for recharge in Sand Canyon, it is assumed that the Resort's existing snowmaking facilities will be used to transfer water into the existing storage pond located at Bear Mountain Ski Resort and a new pump station would be constructed near the pond to convey water through a new pipeline to discharge into Sand Canyon, as shown in Figure 7-3. The pump station and pipeline are sized to convey 380 AF of recharge water over a 6-month period, which equates to approximately 470 gpm. If a joint use arrangement for the Resort's snowmaking facilities cannot be negotiated, constructing new pumping and conveyance facilities to reach Sand Canyon would substantially increase the project cost.

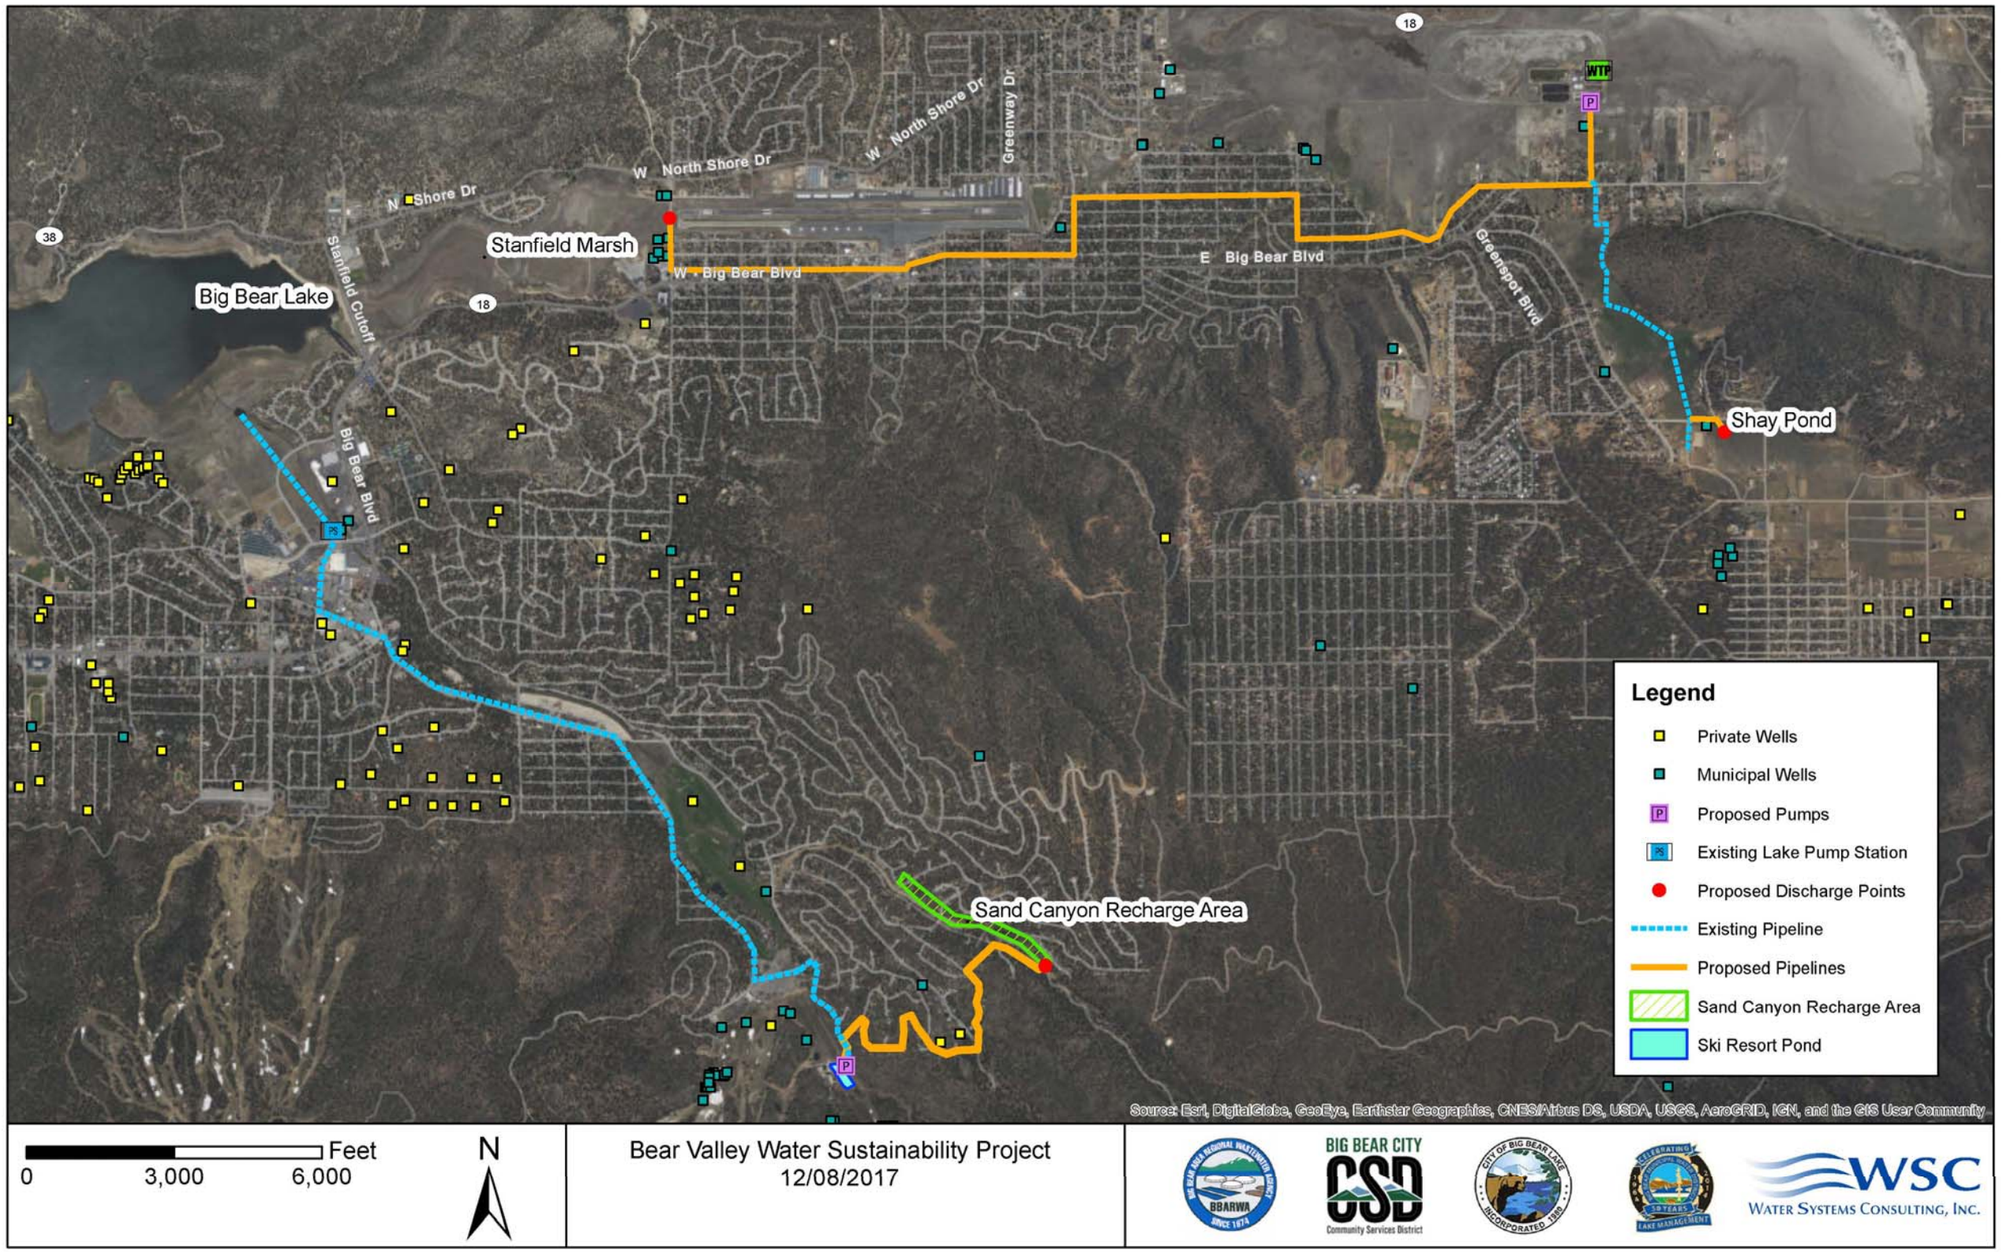

Figure 7-3: Proposed Infrastructure for Bear Valley Lake Alternative

7.5 UNIT COST

The unit cost for the Bear Valley Lake Alternative is shown in Table 7-5. Itemized cost estimates are included in Appendix C.

Table 7-5: Unit Cost for Bear Valley Lake Alternative

Total Capital Cost	Annual O&M	Annual Yield (AF)[1]	30-year Net Present Value (NPV)	Unit Cost ($/AF)[2]
$43,715,000	$2,397,000	1,950	$116,549,000	$1,920

Notes:
1. Based on 10-year average flows. See discussion of yield in Section 7.2, actual yield will vary annually.
2. Unit costs for various alternatives are calculated by dividing the 30-year NPV by the total yield in the 30-year period. See Appendix B for more detail.

7.6 BENEFITS

Implementation of the Lake Alternative provides numerous benefits as described in Section 5, including:

- A consistent high-quality water source to the Marsh to sustain habitat and increase education opportunities for the community and visitors through wildlife observation
- A new source of inflow to the Lake to augment Lake levels, enhance recreational opportunities and aquatic habitat and support water quality improvements. Preliminary models indicate that the implementation of the Lake Alternative will increase Lake levels by nearly 7 feet in 10 years.
- A new and consistent high-quality water source to Shay Pond to sustain habitat for the Unarmored Threespined Stickleback fish, so that the current potable water source can be redirected to serve the community
- A drought proof source of recharge water during dry periods, which will allow blended Lake water to be pumped to Sand Canyon to recharge the groundwater basin to strengthen the sustainability of the groundwater basin during extended droughts
- Flexibility during wet periods to store excess water locally as snow using existing snow making infrastructure. This provides an opportunity to further enhance winter recreation, reduce spills from the Lake, augment spring runoff and increase groundwater recharge. The existing snow making pump and pipeline can also be used to deliver irrigation water to the Bear Mountain Golf Course in the summer, if desired.
- Additional inflow into the Lake may enable BBMWD to modify the current Lake management strategy to minimize spills and flood control releases and optimize releases to ensure that the water can be captured for recharge of the San Bernardino Basin rather than discharged to the ocean.

7.7 ALTERNATIVES COMPARISON

Table 7-6 compares the Lake Alternative to Alternatives 1 through 4 evaluated in the 2016 Study. Capital and O&M Cost estimates from the 2016 Study were escalated to October 2017 and financing assumptions were revised to align with the estimates in this report to provide an even comparison. Note that the unit costs are based on funding 100% the project with loans at a rate of 5% and are expected to be conservative. The project is pursuing multiple grant programs as well as low interest loans which could reduce both the capital payment and interest rate, resulting in a lower unit cost than presented here.

As shown, the Lake Alternative retains more water in the Valley at a lower unit cost than other alternatives, and provides several additional benefits, as discussed in Section 7.6.

Table 7-6. Alternative Comparison

Alternative	Alternative 1 Irrigation (Segment 1.1 Only)	Alternative 2 Greenspot	Alternative 3 Sand Canyon (Low Range)	Alternative 4 Greenspot & Sand Canyon	Lake Alternative
Total Capital Cost	$3,510,000	$47,984,000	$25,057,000	$75,102,000	**$43,715,000**
Annual O&M Cost	$68,000	$1,614,000	$1,232,000	$2,860,000	**$2,397,000**
Recycled Water Yield (AFY)	54	1,000	520	1,750	**1,950**
Unit Cost ($/AF)	$3,950	$3,510	$4,180	$3,310	**$2,110**
Net Present Value	$6,406,000	$105,351,000	$65,226,000	$173,711,000	**$123,309,000**

8 NEXT STEPS

The Lake Alternative is a multi-component project that achieves the Project Team's goal of recovering a lost water supply to increase the sustainability of local water supplies to benefit the entire Valley. As shown in Table 7-6, it is also the most cost-effective alternative that has been identified, in terms of unit cost of water recovered for various beneficial uses.

To move the Lake Alternative into implementation, the following next steps toward several key milestones will need to be pursued in parallel.

8.1 FUNDING APPLICATIONS

Outside funding from various sources will be critical to moving this project forward. Additional outreach to funding agencies and development of a funding and financing strategy is recommended to prioritize funding program pursuits. Potential funding programs that have been identified for the Lake Alternative include:

- $15 million in federal grant funding previously authorized in the Water Resources Development Act of 2007 for water reclamation and distribution by BBARWA. The Project Team is currently pursuing an extension of this authorization, which is set to expire. If the authorization is extended, the project will remain eligible for funding, subject to allocation by the federal government
- California Department of Water Resources Integrated Regional Water Management Implementation Grants, implemented through the Santa Ana Watershed Project Authority
- US Bureau of Reclamation (USBR) WaterSMART Title XVI Water Reclamation and Reuse Program
- United States Department of Agriculture (USDA) Water and Wastewater Disposal Loan and Grant Program
- SWRCB Water Recycling Funding Program Grant and Loan Program
- SWRCB Clean Water State Revolving Fund Loan Program
- US Bureau of Reclamation WaterSMART Water & Energy Efficiency Grant Program (Note: Cannot apply for both USBR Title XVI and WaterSMART programs)
- iBank

8.2 ENVIRONMENTAL IMPACT REPORT

To comply with the California Environmental Quality Act (CEQA), it is anticipated the Project Team will prepare an Initial Study (IS) followed by an Environmental Impact Report (EIR) for the recommended project. In anticipation of applying for federal funding sources, the Project Team may also prepare an Environmental Assessment (EA) and an Environmental Impact Statement (EIS) to comply with the National Environmental Policy Act (NEPA).

Some funding programs require a completed EIR/EIS before a funding application can be considered complete so the schedule.

8.3 PERMIT APPLICATIONS

Ongoing coordination with the permitting agencies will be needed to refine permitting strategies and identify supporting technical studies that will be required. Some specific coordination requirements are expected to include:

- Coordinate with the RWQCB to explore the feasibility of developing a nutrient offset program in exchange for increased nutrient discharge limits for the Marsh/Lake (See Section 6.1.1)
- Continue coordination with DDW to verify the permitting strategy for the Marsh/Lake discharge and the Sand Canyon Recharge Component. Identify technical analysis required to support a determination that the project will not be regulated as Surface Water Discharge (See Section 6.2). Identify technical analysis required to justify recycled water dilution credit from surface water and underflow (See Section 6.3).
- Initiate a long-term study of Stickleback survival in recycled water (See Section 5.2.3)

To obtain an NPDES permit, BBARWA will need to submit a Report of Waste Discharge (ROWD) to the Santa Ana RWQCB, along with an Engineering Report describing the treatment upgrades, effluent characteristics, and proposed uses. The Engineering Report must also be submitted to DDW for review in parallel and DDW will issues findings and conditions for the Sand Canyon recharge component of the project to be incorporated into the discharge permit issued by the RWQCB. The ROWD should be submitted as soon as the Engineering Report is available but no later than six months before the project becomes online, as it typically takes six months for the Regional Board and EPA to review and issue a new permit.

8.4 PRELIMINARY ENGINEERING

A preliminary engineering report is needed to support the development of funding applications, the EIR and the permit applications and can be prepared in parallel with these activities to expedite the implementation schedule. As noted in prior sections of this report, key issues that will need to be evaluated during the preliminary engineering phase include:

- Update WWTP flow projections based on current water use trends to inform appropriate sizing of treatment and disposal facilities (See Section 4.1)
- Update estimates of Lake water level impacts based on anticipated project yield, which may consider the effects of evaporation in the Marsh (See Section 5.1)
- Quantify potential Lake water quality improvements resulting from the implementation of the Lake Alternative (See Section 5.1)
- Refine the estimated recharge potential in Sand Canyon through performance of a pilot infiltration test (See Section 5.3)
- Coordinate with flood control agency to identify technical studies and management practices needed to enable effective joint use of Sand Canyon for flood control and recharge (See Section 5.3)
- Perform a hydrology study to estimate the volume and timing of additional Lake releases under a range of hydrologic conditions so this information can be used in Valley District's model to assess their ability to capture these flows for recharge. (See Section 5.6)

- For Sand Canyon recharge, verify the pathogen control credit that can be achieved by the selected treatment process and identify whether additional underground retention time is needed to achieve the required total credit. (See Section 6.3.3)
- Perform a treatment process alternatives analysis and conduct a pilot study using potential equipment to refine design criteria and validate treatment performance estimates, including nutrient removal capability and RO recovery rates (See Section 7.1)
- Evaluate whether effluent temperature reduction will be required in cooler months (See Section 7.1.1)
- Refine design capacity and RW production estimates based on more detailed flow data, updated future flow projections, and actual MF and RO recovery rates (See Section 7.2)
- Perform a condition assessment and corrosion testing of the exisitng discharge pipeline to Lucerne Valley to determine whether the existing pipeline could accommodate brine conveyance without resulting in significant corrosion. Evaluate whether one of the parallel lines from the concrete balancing main to the LS site could be repurposed for brine conveyance. (See Section 7.3.3)
- Evaluate whether the existing secondary effluent pump station could be repurposed for the new tertiary effluent discharge (See Section 7.4)
- Initiate a water quality sampling program for nutrients, metals, COD, etc. throughout the existing treatment process to support modeling and design of the potential process upgrades needed at the WWTP.

8.5 PUBLIC OUTREACH

A public information program for the Lake Alternative is recommended to engage the community in the development of the project and educate them about the features and benefits. A public information program could take many forms and it is recommended that the Project Team engage in a proactive public outreach program in coordination with other existing or planned outreach programs.

A demonstration project can also be a key feature of a public outreach program because it provides an opportunity to engage and educate the community and improve confidence in the ability of the treatment processes to provide high quality water.

8.6 STAKEHOLDER COORDINATION AND GOVERNANCE

The Project Team should continue the ongoing stakeholder outreach activities they are currently engaged in, including:

- Coordination with each other regarding funding, cost sharing, and ongoing operation and management for the various project components
- Outreach to the Ski Resort to negotiate joint use of their snowmaking facilities for Sand Canyon Recharge and potentially additional snow storage, as well as use of Lake water for irrigation of the Bear Mountain Golf Course
- Collaboration with Valley District to further assess benefits to recharge in the San Bernardino Basin and the potential for a partnership

In addition, an effort should be made to identify potential additional stakeholders that should be engaged early in the project, such as organizations focused on habitat restoration to identify partnership opportunities to further study and enhance the Stickleback habitat

APPENDIX A. SAND CANYON RECHARGE EVALUATION

Technical Memorandum

To: Ms. Laine Carlson
Water Systems Consulting, Inc.

From: Thomas Harder, P.G., C.HG.
Thomas Harder & Co.

Date: 29-Nov-17

Re: Sand Canyon Recharge Evaluation

This Technical Memorandum (TM) presents an evaluation of groundwater recharge potential within Sand Canyon near the City of Big Bear Lake, California (see Figure 1). The evaluation is being conducted as part of a larger study to assess the feasibility of delivering surface water from Big Bear Lake to Sand Canyon using a combination of existing and new pumps and pipeline infrastructure. The water from Big Bear Lake would include treated water stored in the lake from a Big Bear Area Regional Wastewater Agency (BBARWA) treatment plant. Given the source of water, it will be necessary to consider California Division of Drinking Water (DDW) regulations for indirect potable reuse in evaluating the location of recharge within Sand Canyon.

The specific purpose of this evaluation was to consider the following:

1. Given the surface configuration of the Sand Canyon channel and the hydrogeology of the area, how much water can be recharged in Sand Canyon?
2. Where in Sand Canyon would the recharge facilities need to be located in order to meet DDW regulations for subsurface residence time of recharge water prior to extraction?
3. As there is a diluent requirement for recharge of recycled water in surface basins and given that regulations allow for consideration of subsurface underflow as a diluent source, how much natural underflow can be applied to the diluent requirement in Sand Canyon?

Sources of Data

A number of hydrogeological studies have already been conducted in Sand Canyon. These include:

- Geoscience, 1990. Geohydrologic Characteristics and Artificial Recharge Potential of the Sand Canyon Area. Dated December 1990.
- Geoscience, 2002. Results of Drilling, Construction, Testing and Pump Design for the Sheephorn Well. Dated February 1, 2002.

Analysis Methodology

Geoscience (1990) had previously conducted a travel time analysis for the Sand Canyon area using a numerical groundwater flow model. The downgradient extent of recharge ponds was identified as the point where Teton Road crosses the channel (see Figure 2). Based on this analysis, the travel time to the proposed downgradient extraction wells (proposed to be near TH-5) was more than six months. However, the analysis was based on a range of assumed hydraulic conductivity of 13 ft/day to 40 ft/day. Further, the range of effective porosity was 0.15 to 0.2. These values are relatively high and estimated based on the lithology of sediments encountered during drilling of test boreholes in the area. Subsequent pumping tests from the City of Big Bear Lake Department of Water's (the City's) Sheephorn Well (see Figure 2) indicate that the hydraulic conductivity of the aquifer is less than 1 ft/day. Further, other pumping tests in the area have shown that the effective porosity (which is equivalent to the specific yield in an unconfined aquifer) is on the order of 0.04.

In order to reevaluate the potential travel time and mounding from recharge basins upstream of Teton Road using updated aquifer properties, TH&Co developed a two-dimensional analytical flow model of the Sand Canyon area (see Figure 3 for model area). The analysis was conducted for steady state conditions using the model code WinFlow[1]. All travel time analyses were conducted using the particle tracking feature which allows for the estimation of groundwater travel time between two points from advective groundwater flow. The analysis incorporated the following assumptions:

- The area of the Sand Canyon channel identified for recharge is shown on Figure 3 and is equivalent to approximately 4.2 acres.
- The volume of water applied to the Sand Canyon recharge area was based on an assumed recharge rate of 0.5 ft/day, applied to the recharge basins over a 6-month period. Thus, the total volume of managed recharge for the simulation was 384 acre-ft.

[1] WinFlow Version 3, Environmental Simulations Inc., 2003.

- The analysis was conducted with the Sheephorn Well pumping at a rate of 125 gallons per minute (gpm) for 7 hours per day and the Sand Canyon Well pumping at a rate of 115 gpm for 9 hours per day.
- The initial groundwater levels were conditioned to a groundwater level contour map published by Geoscience (1990)[2] (see Figure 3). This contour map was generated based on data collected during a relatively dry hydrologic period.
- The hydraulic conductivity of the aquifer beneath the basins is assumed to be 1 ft/day.
- The porosity of the aquifer sediments is assumed to be 0.04.
- The sediments in the vadose zone and aquifer are homogeneous.

Findings

Recharge Potential

The primary limit to recharge rates in the Sand Canyon area appears to be available subsurface storage space to accommodate the groundwater mound. The target maximum groundwater level relative to the land surface was 20 ft below ground surface. Previous studies in the Big Bear area have shown that this depth is protective of liquefaction. This groundwater level was achieved at a recharge rate of 2.1 acre-ft/day in the recharge area, with the shallowest groundwater levels occurring beneath the furthest downgradient recharge basins. At a recharge rate of 2.1 acre-ft/day, the maximum predicted recharge for this study was approximately 380 acre-ft/yr, based on a six-month recharge period.

Recharge Water Subsurface Travel Time to the Nearest Downgradient Well

The particle tracking analysis shows that the recharge water will reach the nearest production well (Sheephorn Well) in a little more than approximately 13 months (see Figure 4). Assuming the Sand Canyon recharge project would fall under the definition of a Groundwater Replenishment Reuse Project (GRRP), per DDW regulations, the required subsurface retention time for the recharge water is 2 months. For preliminary recharge siting purposes, a "credit" of 0.25 is applied for travel time calculations using an analytical model, as was done for this analysis. Thus, the credited retention time is interpreted to be 9.75 months (39 x 0.25). This credited retention time is less than the retention time simulated for this analysis (13 months), indicating that the sites simulated are feasible based on the data assumptions in the analysis.

The limiting factors for recharge capacity, as identified by this analysis, were infiltration rate and groundwater mounding in proximity to the land surface. Further data collection will be necessary to determine the total recharge potential of the Sand Canyon area of interest. The most

[2] Geoscience, 1990. Geohydrologic Characteristics and Artificial Recharge Potential of the Sand Canyon Area.

representative infiltration rates can be obtained through a pilot infiltration test. The test would consist of a controlled release of water into a portion of the channel where the water can be dammed up and temporarily ponded. The water level stage in the ponded area can be measured using a staff gage. Once the depth of the ponded area was sufficient (1 to 2 ft deep), the discharge into the channel would be discontinued and the rate of infiltration measured using the staff gage. Optimally, a succession of multiple wetting and drying cycles would be conducted to obtain an average infiltration rate. If possible, the test should also be conducted at multiple locations along the channel, to determine differences in infiltration rate with location.

Native Subsurface Underflow to the Recharge Area

As the aquifer beneath the Sand Canyon area is conceptualized as being unconfined, native subsurface underflow contribution to the portion of the aquifer beneath the recharge area was estimated based on the Dupuit Equation[3], which is expressed as:

$$Q = 0.5K\left(\frac{(h_1 - h_2)^2}{L}\right)$$

Where:

Q	=	Subsurface flow, (acre-ft)
K	=	Hydraulic Conductivity, (ft/day)
h_1	=	Initial Hydraulic head, (ft amsl)
h_2	=	Ending Hydraulic head, (ft amsl)
L	=	Flow Length (ft)

The change in hydraulic head was determined based on the contour map published in Geoscience (1990). The hydraulic conductivity was assumed to be 1 ft/day based on a pumping test conducted in the Sheephorn Well. A summary of the underflow analysis is provided in Table 1. The volume of underflow that may be applied toward the diluent requirement will likely depend on DDW review and interpretation of the data. A range of potential diluent credit was developed such that the low end of the range represents the underflow directly beneath the Sand Canyon channel and the high end of the range represents the entire flow net that ultimately contributes

[3] Fetter, 1994. Applied Hydrogeology, 3rd Edition. MacMillan College Publishing Co.

underflow to the Sand Canyon area, as shown on Figure 1. The range is approximately 58 acre-ft/yr to 247 acre-ft/yr (see Table 1).

APPENDIX B. FINANCIAL ASSUMPTIONS

Planning Level Cost Estimates

The cost opinions (estimates) included in this Study are prepared in conformance with industry practice and, as planning level cost opinions, will be ranked as a Class 4 Conceptual Opinion of Probable Construction Cost as developed by the Association for the Advancement of Cost Engineering (AACE) Cost Estimate Classification System (19). The AACE classification system is intended to classify the expected accuracy of planning level cost opinions, and is not a reflection on the effort or accuracy of the actual cost opinions prepared for the study. According to AACE, a Class 4 Estimate is intended to provide a planning level conceptual effort with an accuracy that will range from -30% to +50% and includes an appropriate contingency for planning and feasibility studies. The conceptual nature of the design concepts and associated costs presented in this Study are based upon limited design information available at this stage of the projects. These cost estimates have been developed using a combination of data from RS Means CostWorks®, recent bids, vendor supplied data, experience with similar projects, current and foreseeable regulatory requirements and an understanding of the necessary project components. As specific projects progress, the design and associated costs could vary significantly from the project components identified in this Study. Cost opinions are planning level and may not fully account for site-specific conditions that will affect the actual costs, such as soils conditions and utility conflicts.

For projects components where applicable cost data is available in RS Means CostWorks® (e.g. pipeline installation), cost data released in Quarter 3 of 2017, adjusted for San Bernardino, California, is used. Material prices were adjusted in some cases to provide estimates that align closer with actual local bid results. For projects where RS Means CostWorks® data is not available, cost opinions are generally derived from bid prices from similar projects, vendor quotes, material prices, and labor estimates, with adjustments for inflation, size, complexity and location.

Cost opinions are in 2017 dollars (ENR 20 City Average Construction Cost Index of: 10,817 for October 2017).

Markups and Contingencies

For the development of the planning level cost estimates, several markups and contingencies are applied to the estimated construction costs to obtain the total estimated project costs. The markups are intended to account for costs of engineering, design, administration, and legal efforts associated with implementing the project (collectively, Implementation Markup). Contingency accounts for additional construction costs that could not be anticipated at the time of this analysis. A summary of the markups and contingencies applied are presented in the table below.

	Markups and Contingencies
	Construction Subtotal
+	20% of Construction Subtotal for Contingency
+	40% of Construction Subtotal for Implementation
=	**Total Capital Cost**

Unit Cost and Net Present Value

To comply with federal funding program requirements, the net present values (NPV) are calculated for each alternative and treatment option. The NPVs account for capital costs (one-time costs associated with each alternative) and operation and maintenance (O&M) costs (i.e. electrical and maintenance) over a 30-year period. O&M costs are subdivided into Conveyance Pumping Energy costs and Non-Energy costs to enable these costs to be escalated at different rates in the future, recognizing that energy costs are anticipated to rise faster than non-energy costs.

The assumptions used to calculate the costs for each alternative are summarized in the table below.

Assumption	Current Value	Annual Escalation Rate	Description
Loan Terms	100% loan for 30-year loan term with a 5% capital financing rate		Loan term based on CWSRF loan term. Capital financing rate of 5% is expected to be conservative as the project may be eligible for low interest loans.
Discount Rate			A Discount Rate of 3% is used for the NPV
O&M – Conveyance Pumping Energy	$ 0.14/ KW-hr	3.0 %	Energy escalation based on US Energy Information Administration (USEIA) previous 5-year average electricity rate data for California Commercial rates.
O&M – Non Energy	Varies by facility type, based on capacity or capital cost	2.4%	Non-energy escalation based on California CCI previous 5-year average

EXECUTIVE SUMMARY

Big Bear Lake is an important natural resource that provides extensive recreational, economic, ecological, and aesthetic benefits for the local community as well as the larger inland Southern California region. As with all other natural and man-made lakes in Southern California, the lake is subject to dramatic variability in water surface elevation; surface elevations reached as low as -48.5 feet (ft) relative to dam crest (72.33 ft maximum depth) in November 1961, corresponding to a volume of less than 1,000 acre-feet (af) and a lake surface area on the order of 200-300 acres during the extended drought in the late 1950's and early 1960's. Big Bear Municipal Water District (BBMWD) was subsequently formed in 1964 to manage and help stabilize the water level in Big Bear Lake. The region's natural hydrology includes severe protracted droughts and is influenced by the Pacific Decadal Oscillation (PDO) and El Nino-La Nina climate systems, which makes lake level stabilization a tremendous challenge. This wide variability in lake level, in turn, can have significant impacts on beneficial uses of the lake. Monitoring data collected primarily by the Big Bear City Community Services District (BBCCSD), BBMWD, and the Big Bear Lake Nutrient Total Maximum Daily Load (TMDL) group over the past decade underscore both the variability in regional hydrology and lake levels, and the consequences of extended periods of low runoff on water quality conditions. To minimize the impacts of frequent droughts, Replenish Big Bear was developed to recover and use a water resource currently discharged outside of the watershed.

This study assessed the overall conditions, ecological health and water quality in Big Bear Lake, and evaluated the potential influence on lake health of Replenish Big Bear. Three treatment alternative strategies (Treatment Alternatives), composed of advanced nutrient removal and reverse osmosis (RO) technologies, were evaluated:

(i) Alternative 1: TIN & TP Removal
(ii) Alternative 2: 70% RO (in addition to TIN & TP Removal)
(iii) Alternative 3: 100% RO (in addition to TIN & TP Removal)

This study included an analysis of available water quality data, development of a 2-D hydrodynamic-water quality model (CE-QUAL-W2), and application of the model to evaluate lake conditions with Replenish Big Bear that focused on the period from 2009-2019. This period was selected based upon a number of factors, including the wide range of hydrologic and water quality conditions in the lake, and availability of extensive lake monitoring and meteorological data, as well as some watershed monitoring data. Model simulations from 2020-2050 were also conducted to assess possible future conditions in Big Bear Lake under different hydrologic scenarios and Replenish Big Bear discharge alternatives. The routing of Replenish Big Bear water through Stanfield Marsh was also explored in greater detail to provide better understanding of the possible role of the marsh in nutrient attenuation.

Analysis of Water Quality Data

To augment the water quality information provided in the TMDL annual reports, additional conventional statistical and advanced machine learning analyses were conducted. Analyses focused on chlorophyll-a as the key response variable. The ratio of total nitrogen (total N) to total phosphorus (total P), often used to identify nutrient limitation, confirm P-limitation principally in place regulating algal production. Correlations developed between total P, total N, total inorganic N (TIN) and chlorophyll-a for each of the 4 TMDL sampling stations (n=150 for each station) indicate relatively weak correlations with nutrient concentrations (e.g., R^2-values of 0.08, 0.19, 0.21 and 0.31 between chlorophyll-a and total P for TMDL stations #1, 2, 6 and 9, respectively). R^2 values quantify the variance in dependent variable (chlorophyll-a) captured with the independent variable (e.g. total P), so it is clear that phytoplankton levels are a more complex function of conditions in the lake. Slightly higher R^2 values were in fact noted with total N (R^2=0.22-0.53), while chlorophyll-a was uncorrelated with TIN. Concentration of chlorophyll-a was also relatively weakly correlated with TDS and lake level; multiple linear regression (MLR) using all these variables yielded R^2-values of 0.31-0.55 depending upon TMDL sampling station.

Since significant portions of variance in observed chlorophyll-a concentrations remained uncaptured using MLR, machine learning was also evaluated. Machine learning, which is starting to be used in water quality applications, is often able to more effectively elucidate trends in complex datasets. Random forest and gradient-boosted regressor algorithms applied to TMDL station #1 data using day of year, lake level, TDS concentration and windspeed were able to capture most (0.92-0.96) of the observed variance in chlorophyll-a for the 10-yr 2009-2018 training set, notably without considering concentrations of total N or total P. For comparison, MLR using this same set of independent variables captured 0.43 of variance in observed chlorophyll-a concentrations. The gradient-boosted regressor model also demonstrated strong forecasting power, capturing 0.73 of variance in predicted chlorophyll-a concentrations of the 2019 data set (compared with 0.36 for the equivalent MLR model). Statistical analyses highlighted that multiple factors regulate chlorophyll-a concentrations in complex ways; machine learning was able to identify relationships and develop regressor models that reproduced and forecasted concentrations of chlorophyll-a with considerable accuracy.

Water column profile data were also used to quantify rates of internal nutrient recycling and areal hypolimnetic oxygen demand (AHOD). Internal nutrient recycling rates have been measured on a limited number of dates since 2002 using the laboratory core-flux method, while AHOD has not previously been measured at the lake. The *in situ* hypolimnetic mass balance approach using measured water column concentrations of ammonium as N (NH_4-N) and orthophosphate as P (PO_4-P) yielded recycling rates for 2010-2011 and 2015-2017 that were similar to previously measured values confirming the importance of nutrient recycling in lake biogeochemistry and nutrient budgets, and establishing the reliability of alum treatments in suppressing PO_4-P release. The analysis also yielded *in situ* estimates of early summer AHOD rates at TMDL station #1 of approximately 0.5 g/m^2/d.

Development of 2-D Hydrodynamic-Water Quality Model

A 2-D (longitudinal-vertical) hydrodynamic -water quality model for Big Bear Lake was developed using CE-QUAL-W2. The model quantifies heat and water budgets, 2-D hydrodynamics, and predicts concentrations of nutrients, dissolved oxygen (DO), chlorophyll-a and other parameters. The 2-D (longitudinal-vertical) representation assumes the primary gradients in water column properties and water quality are in the vertical and longitudinal directions, and well-mixed in the lateral direction; model branches were added for embayments that allow a quasi-3-D representation of the lake. The model requires extensive bathymetric, hydrologic, meteorological, water quality, and other data. The 2-D laterally-averaged model grid was developed from the bathymetric survey data collected by Fugro Pelagos Inc. (2006). Hydrologic data defining inflows, outflows, and withdrawals were developed from annual Big Bear Water Master reports. Hourly meteorological conditions were taken from Big Bear Airport and California Irrigation Management Information System (CIMIS) Station #199 located at the golf course. Data included solar shortwave radiation, air temperature, dewpoint temperature, windspeed, wind direction and cloud cover. Cloud cover was determined from sky cover conditions reported in METAR data for the airport. The model was calibrated against measured lake level, *in situ* profiles of temperature and DO, and laboratory analyses of water samples collected at the lake for 2009-2019. The model was first developed and calibrated for lake level, water column temperature profiles and TDS, where generally very good agreement was achieved (mean absolute errors of 3.6 cm, 0.79-0.89 °C, and 11.9 mg/L, respectively).

Following this, model calibration to water quality data was conducted. The model included external nutrient loading from the watershed, atmospheric deposition, internal nutrient recycling, and nutrient uptake and release associated with macrophyte and epiphyton growth, senescence and death. Two algal groups were simulated, included one representing cyanobacteria capable of N_2-fixation. The 1^{st}-order dynamic sediment model was combined with the 0^{th}-order SOD model to simulate nutrient recycling and DO uptake in the surficial bottom sediments. Relative root mean square error was 17.7% for total P, 18.0% for total N, 29.5% for TIN, and 24.0 % for chlorophyll-a. Mean absolute errors for DO ranged from 1.02 – 1.40 mg/L for the 4 TMDL sampling stations.

Application of Model to Evaluate Conditions with Replenish Big Bear

The model was then used to predict conditions in Big Bear Lake from 2009-2019 that would reasonably be expected with water from Replenish Big Bear delivered to the lake. Supplementation of natural flows with 1,920 af/yr of Replenish Big Bear water adds about 0.2 meter (m) annually to the lake relative to levels observed in 2009-2019 (baseline), and which accrues over time such that the lake was predicted to be 1.7 m higher in late 2018 compared to the level present at that time. Supplementation also increased predicted lake volumes and surface areas, with lake area about 300 acres (16%) larger in late 2018 compared with actual area (approximately 2,200 acres vs 1,900 acres, respectively). TDS levels in the lake were strongly influenced by level of treatment and TDS concentrations in the Replenish Big Bear water; Alternative 1 water with TIN and total P removal was projected to have a TDS of 450 mg/L, while addition of RO to further treat 70% and 100% of the water (Alternatives 2 and 3) was assumed

to reduce effluent TDS to 150 and 50 mg/L, respectively. Addition of 1,920 af/yr of Alternative 1 water significantly increased TDS levels in the lake, increasing average predicted TDS from 251 mg/L for the baseline (natural) condition for 2009-2019 to 300 mg/L, while Alternatives 2 and 3 were predicted to yield lower average TDS concentrations of 244 and 226 mg/L, respectively. Exceedance of the TDS water quality objective of 175 mg/L was predicted to occur 97.6% of the time for both the baseline condition and for Alternative 2, while exceedance frequency increased to 100% for Alternative 1 and was reduced to 93.3% for Alternative 3.

Nutrient concentrations in the Replenish Big Bear water also varied markedly with treatment, with total N and total P concentrations in Alternative 1 effluent being about 6-9 times higher than median watershed concentrations, while effluent concentrations in Alternative 2 were projected to be 1.8-2.3 times larger and Alternative 3 being about 0.4-0.8 times that of median watershed values. The increased nutrient loading from Alternative 1 had a strongly detrimental effect on water quality, increasing average concentrations over 2009-2019 baseline of total N by about 50%, total P by 70%, and chlorophyll-a by 300%. In comparison, further treatment of effluent with RO yielded average concentrations comparable to (Alternative 2) or slightly improved (Alternative 3) relative to the baseline (natural no-project) condition.

Predicted Long-Term Future Conditions with Replenish Big Bear

Simulations for 2009-2019 were extended to 2050 to evaluate possible long-term conditions in the lake under natural hydrologic variability with and without supplemental water from Replenish Big Bear. Since detailed meteorological and hydrological conditions for the future are not known *a priori*, existing meteorological and flow data for 2009-2019 were used as the basis for forecasts. 2009-2019 included extreme ranges in rainfall, runoff and air temperatures; assuming this range is broadly representative of likely future meteorological and hydrologic conditions, Monte Carlo techniques were used to randomly select 100 different 30 year annual records from this set of data. From these 100 different hydrologic scenarios, the 5^{th}-, 50^{th}- and 95^{th}-percentile 30 year average annual flow records and corresponding meteorological conditions were used as temporal boundary conditions for predictions of future conditions in the lake. The 5^{th}-percentile corresponds to an average inflow rate of 8,646 af/yr and represents extended drought, while the 50^{th}-percentile (median) corresponds to intervals of high runoff and drought (average annual inflow of 10,595 af/yr) comparable to 2009-2019, and the 95^{th}-percentile represents a period of protracted above average rainfall and runoff (average annual inflow of 12,225 af/yr). (Note that since precipitation and runoff are log-normally distributed, the above arithmetic mean values understate the range in runoff within the simulation intervals; that is, a single high runoff year can significantly skew upward average values during a period of protracted drought.)

Supplementation with Replenish Big Bear was also predicted to increase average long-term (2009-2050) conditions in the lake that varied under the 3 hydrologic scenarios. Under the 50^{th}-percentile hydrologic scenario, Replenish Big Bear was predicted to increase average lake level by 1.5 m, lake volume by nearly 13,000 af, and lake area by 260 acres relative to the predicted long-term baseline (no-project) condition. Water quality varied with level of treatment, with Alternative 1 nearly doubling predicted long-term average concentrations of TDS, total P and

total N and quadrupling average predicted chlorophyll-a levels. Long-term simulations indicate slight increases in average TDS, total P and total N and modest increase in chlorophyll-a for Alternative 2, and generally slight reductions or no significant change in concentrations with Alternative 3. Supplementation was predicted to have more substantial effects under the 5^{th}-percentile runoff scenario, with increased average lake level of 3.4 m, increased volume of 16,104 af, and an additional average 638 surface acres (about 40% increase) relative to baseline. As with the median runoff scenario, supplementation with Alternative 1 effluent substantially degraded water quality, while further treatment (Alternatives 2 and 3) was predicted to result in comparable or slightly improved water quality in the lake. Effects of Replenish Big Bear were more muted at the 95^{th}-percentile runoff scenario, when supplementation is less important, owing to the lower overall contributions of water and TDS and nutrients relative to the watershed.

Routing of Supplemental Water Through Stanfield Marsh

Simulations with Replenish Big Bear involved routing of effluent through Stanfield Marsh, where some nutrient uptake could be expected. Simulations indicate net removal of total P through the Marsh with Alternative 1 and Alternative 2 effluent, while simulations predicted that the Marsh would be a modest source of total P to Alternative 3 water with very low influent concentrations. Interestingly, the Marsh was predicted to be a source of total N across all levels of treatment, due to sediment decay, and some N_2-fixation and subsequent decay in response high PO_4-P concentrations and high TN:TP ratios in the effluent. Further work is needed, however, to better understand the role of the Marsh as a net sink and/or source for nutrients.

Summary

Lake conditions and water quality in Big Bear Lake varied significantly over 2009-2019, with wide variations in lake level, volume and surface area, as well as concentrations of TDS, nutrients and chlorophyll-a. Statistical, machine learning and hypolimnetic mass balance analyses provided valuable new information about water quality in Big Bear Lake, while CE-QUAL-W2 was able to reproduce observed trends in lake conditions. Supplementation of natural runoff with Replenish Big Bear water significantly increased lake levels, volumes and surface areas, especially during periods of drought, with resulting recreational, aesthetic, community and related benefits. The level of treatment had dramatic effects on water quality, however. Nutrient removal (Alternative 1) was not sufficient to protect water quality, although nutrient removal with further treatment (Alternatives 2 and 3) was predicted to yield water quality comparable to or slightly improved relative to baseline conditions.

I. INTRODUCTION AND STUDY OBJECTIVES

The Replenish Big Bear Team, a collaborative regional water resources program being implemented by Big Bear Area Regional Wastewater Agency (BBARWA), Big Bear City Community Services District (BBCCSD), Big Bear Lake Department of Water and Power (BBLDWP), Big Bear Municipal Water District (BBMWD) and the Bear Valley Basin Groundwater Sustainability Agency (BVBGSA), engaged Professor Emeritus Michael A. Anderson (Dr. Anderson), who has in-depth knowledge of the Big Bear Lake (Lake), to evaluate the Lake water quality conditions and assess the potential impacts of the Replenish Big Bear project. This study was prepared in response to the Santa Ana Regional Water Quality Control Board (Santa Ana Water Board) staff's need to have a better understanding of the Lake's health to consider approving a discharge above current Basin Plan water quality objectives (WQOs) or the Nutrient Total Maximum Daily Load (Nutrient TMDL) for Dry Hydrologic Conditions.

This study assesses the overall conditions, ecological health, and water quality in Lake, and evaluates the potential influence on lake health of three treatment alternative strategies (Treatment Alternatives) to supplement the natural water supply to the lake. These Treatment Alternatives are composed of advanced nutrient removal and reverse osmosis (RO) technologies:

(i) Alternative 1: TIN & TP Removal
(ii) Alternative 2: 70% RO(70% RO + 30% TIN & TP Removal)
(iii) Alternative 3: 100% RO

A. Project Background

Replenish Big Bear was developed in an effort to help protect Big Bear Valley (Valley) and the Santa Ana Watershed from the impacts of drought and variable precipitation by recovering a water resource currently discharged outside of the watershed. Replenish Big Bear is comprised of three independent projects, which will be implemented separately in the following progression, as practicable:

- Effluent discharge to Stanfield Marsh (and subsequently to the Lake) and Shay Pond;
- Use of Lake water for landscape irrigation of the local golf course; and
- Use of Lake water for groundwater recharge in Sand Canyon.

The first project, and primary regulatory driver, includes treatment upgrades at the BBARWA wastewater treatment plant (WWTP) to produce highly treated effluent for discharge to Shay Pond and Stanfield Marsh, which flows into the lake. This study evaluates the water quality in the lake and assesses impacts of discharge through Stanfield Marsh. For redundancy purposes, BBARWA is also seeking to maintain its current discharge location in Lucerne Valley, where undisinfected secondary effluent is currently conveyed to irrigate crops used for livestock feed. These new discharge points will allow BBARWA to minimize discharge of treated effluent outside of the watershed, which will increase Lake levels to better support beneficial uses including recreation and habitat, particularly in times of drought. Additionally, discharge to Shay Pond will replace potable water currently discharged to maintain the water flow through the pond. Figure

1 shows the project components for this first project, which is referred to as the effluent discharge project.

The other two projects will utilize lake water for (i) landscape irrigation at the local golf course to achieve in lieu recharge of the groundwater basin and (ii) direct groundwater recharge in Sand Canyon. These projects are not planned for any time soon.

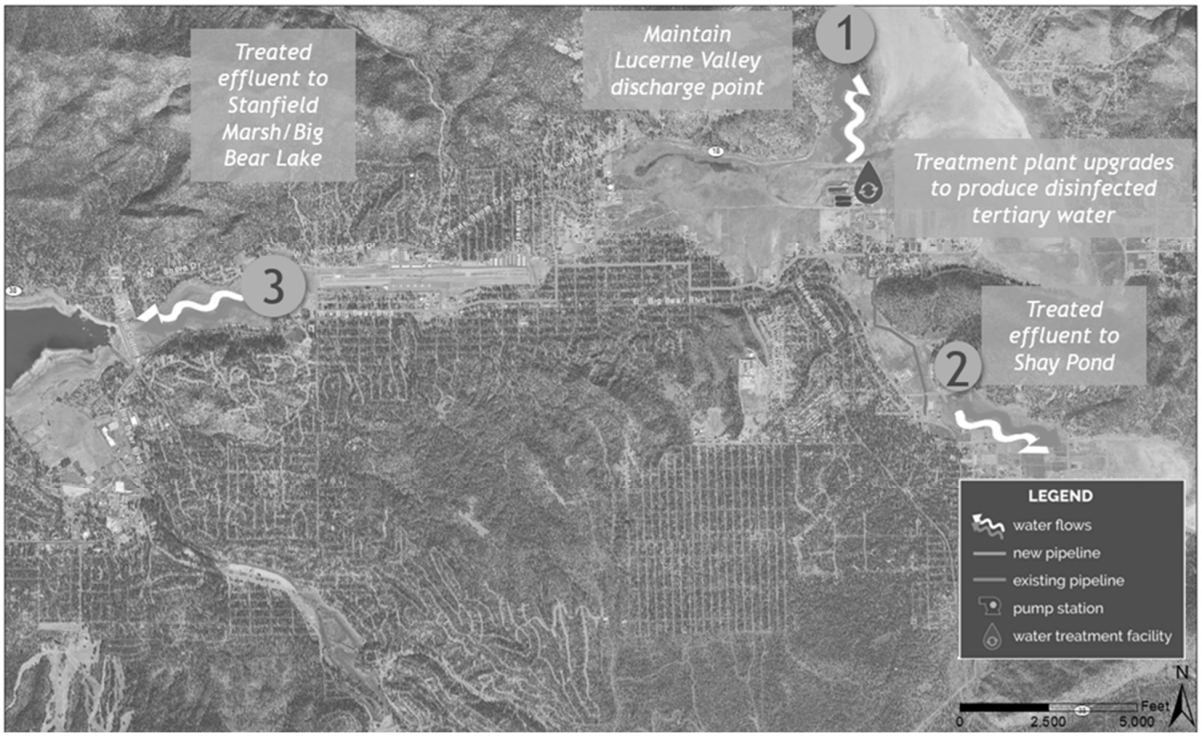

Figure 1. Effluent discharge project components and overview of discharge locations

B. Lake Background

Big Bear Lake is an important resource that provides extensive recreational, economic, ecological, and aesthetic benefits for the local community as well as the larger inland southern California region. Together, Stanfield Marsh and the Lake have a surface area of nearly 3,000 acres, a storage capacity of 73,320 af, and an average depth of 32 feet (ft). Stanfield Marsh and the Lake are both waters of the State of California (State) and United States (U.S.), which have several designated beneficial uses. For reference, Table 1 shows the designated beneficial uses of the Lake and Stanfield Marsh per the 1995 Water Quality Control Plan for the Santa Ana Basin Plan (Basin Plan), as amended in 2008, 2011, 2016, and 2019. In addition, the Nutrient TMDL was adopted to address concerns with phosphorus and nitrogen impacts on the lake. Table 2 presents the Lake regulatory limits set to protect the Lake benefits.

Note: **Bolded** constituents were identified as priority in previous regulatory meetings and are specifically evaluated in this study.		

The Lake is located about 6,743 ft (2,055 m) above mean sea level (MSL) in the San Bernardino Mountains in San Bernardino County. The Lake was formed following construction of the Bear Valley Dam in 1883-1884 to serve as an irrigation supply for the citrus industry in the downstream Redlands-San Bernardino communities. Since that time, the Lake has served as a vital engine for economic growth in the Valley, and the region has developed into a year-round destination with extensive recreational and commercial activities, primary and secondary residences, vacation properties and hospitality, and other services.

As with all other natural and man-made lakes in Southern California, the Lake is subject to dramatic variability in water surface elevation; surface elevations reached as low as -48.5 ft relative to dam crest (72.33 ft maximum depth) in November 1961, corresponding to a volume of less than 1,000 af and a lake surface area on the order of 200-300 acres during the extended drought in the late 1950's and early 1960's. BBMWD was subsequently formed in 1964 to manage and help stabilize the water level in the Lake. The region's natural hydrology includes severe protracted droughts and is influenced by the Pacific Decadal Oscillation (PDO) and El Nino-La Nina climate systems (Kirby, 2010), which makes lake level stabilization a tremendous challenge.

This wide variability in Lake level, in turn, can have dramatic impacts on recreational, economic, and aesthetic values of the Lake, as well as ecological conditions and Lake water quality.

Monitoring data collected over the past decade underscore both the variability in regional hydrology and Lake levels, and the consequences of extended periods of low runoff for water quality conditions in the Lake.

C. Objectives

This study (i) analyzed available historical data on Lake conditions to improve quantitative understanding of water quality in the Lake and the interactions and relationships of key causal and response parameters through statistical and advanced machine learning approaches; (ii) developed and calibrated a 2-D hydrodynamic-water quality model using available historical data to develop an improved process-level understanding of water quality; (iii) assessed conditions in the Lake under natural variable hydrology and climate change through the application of the 2-D hydrodynamic water quality model; and (iv) evaluated, through model simulations, Lake conditions with different treatment alternatives for the proposed Replenish Big Bear project. Phosphorus, nitrogen and total dissolved solids (TDS) are the primary constituents of interest with respect to impacts to the Lake and its beneficial uses.

II. ANALYSIS OF AVAILABLE WATER QUALITY DATA

As illustrated in the Baseline Assessment Tech Memo (WSC, 2020), the Lake is subject to widely varying lake volumes and wide ranges in nutrient, TDS, and chlorophyll-a concentrations. Extension of the analysis provided in the Baseline Assessment Tech Memo (WSC, 2020) was conducted to include additional calculations, regressions, and machine learning to better understand the factors, relationships, and interactions governing water quality. Field and laboratory data for TMDL stations #1 (Dam), #2 (Gilner Point), #6 (Mid-lake) and #9 (Stanfield) over the 2009-2019 time period formed the basis for the analyses. These monitoring stations are shown in Figure 2.

Linear regressions and other statistical analyses are commonly used to identify factors affecting water quality in lakes. Machine learning is now starting to be used for water quality assessments (Chou et al., 2018; Ahmed et al., 2019), including short-term forecasting of algal blooms (Park et al., 2015), owing its ability to often elucidate relationships within complex datasets. Supervised machine learning requires a robust dataset on which to train and validate models. BBMWD has developed and maintained a high quality Lake monitoring program, and has an excellent dataset that was used to train and test different supervised machine learning models. This dataset provides an empirical, data-based approach to identifying and understanding relationships between causal and response variables and predicting water quality in the Lake.

Data were also used where possible to quantify rates of important processes operating within the Lake. For example, increases in total P and total inorganic nitrogen (TIN) concentrations are routinely recorded in late summer/early fall that are thought to be associated with lake mixing (WSC, 2020). Hypolimnetic and/or water column mass balance calculations often allow calculation of internal nutrient recycling rates from bottom sediments (Cooke et al., 2005). Such calculations also provide comparisons with previous laboratory core-flux measurements (Anderson and Dyal, 2003), and allow evaluation of effects of runoff, lake level, and other factors on internal nutrient loading, which is recognized as an important source of nutrients to the Lake (contributing, for example, an estimated 52% of total nitrogen and total P loading under a dry scenario) (Santa Ana Water Board, 2005).

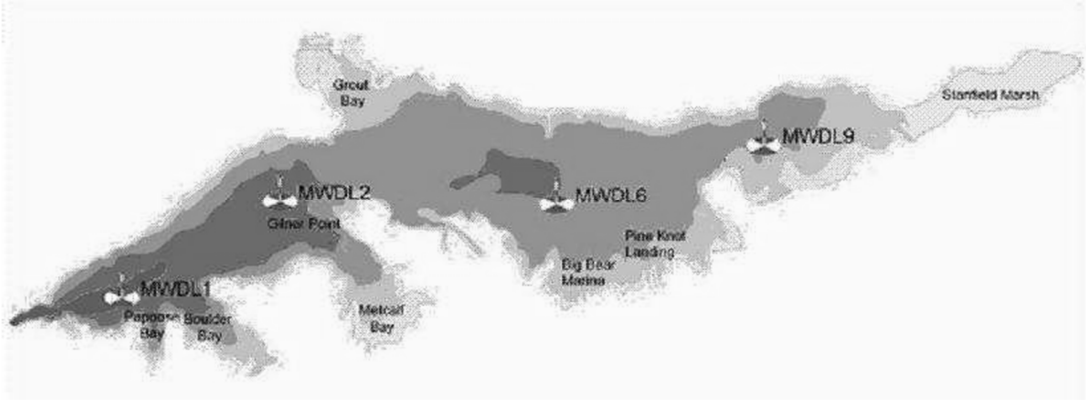

Figure 2. Big Bear Lake TMDL sampling station.

A. Factors Regulating Algal Productivity in Big Bear Lake

1. Statistical Analysis

The TMDL annual water quality reports provide water quality reports, time-series data, and summary statistics, so this section focuses on select statistical analyses of TMDL water quality data. The Lake is generally considered to be P-limited; the ratio of TN to TP concentrations (TN:TP ratio) is reflective of the elemental composition of phytoplankton, with P-limitation generally recognized at TN:TP ratios >20, and N-limitation at TN:TP ratio <5 (Thomann and Mueller, 1998). Photic zone TN and TP concentrations for the 2009-2019 time period were used to calculate TN:TP ratios at the four stations to confirm that P-limitation typically exists in the Lake. Median TN:TP ratios were 27-28 at the Dam, Gilner Point, and Mid-lake stations, but somewhat lower (21.1) at the Stanfield station (Table 3). The TN:TP ratios exhibited considerable variability, so values have been plotted as cumulative distribution functions (Figure 3). Based on these data, the Lake can be considered to be P-limited about 70% of the time and co-limited about 30% of the time. By this measure, N-limitation was present only 1-2% of the time, thus supporting efforts to constrain external loading and internal recycling of P in the Lake.

Table 3. Summary statistics for total nutrients and chlorophyll-a concentrations at the four TMDL sampling stations for 2009-2019 (photic zone).

Parameter	Value	Dam	Gilner Point	Mid-Lake	Stanfield
Total P	Median	0.036	0.040	0.040	0.051
	25-75%	0.024 – 0.050	0.024 – 0.060	0.026 – 0.068	0.033 – 0.088
	Min-Max	0.005 – 0.150	0.005 – 0.210	0.005 – 0.200	0.008 – 0.400
Total N	Median	1.12	1.10	1.16	1.22
	25-75%	0.92 – 1.26	0.93 – 1.27	0.94 – 1.33	0.96 – 1.53
	Min-Max	0.028 – 2.14	0.19 – 3.25	0.17 – 2.43	0.28 – 2.89
Chlorophyll-a	Median	9.4	10.9	11.7	15.1
	25-75%	6.1 – 14.6	6.7 – 16.0	7.5 – 16.5	8.8 – 27.0
	Min-Max	0.9 – 51	0.5 – 205	2.0 – 106	1.8 – 150
TN:TP	Median	28.2	27.3	27.2	21.2
	25-75%	19.1 – 40.4	18.9 – 38.2	17.4 – 39.0	14.8 – 30.8
	Min-Max	7.3 – 162	3.4 – 244	4.0 – 284	3.5 – 147

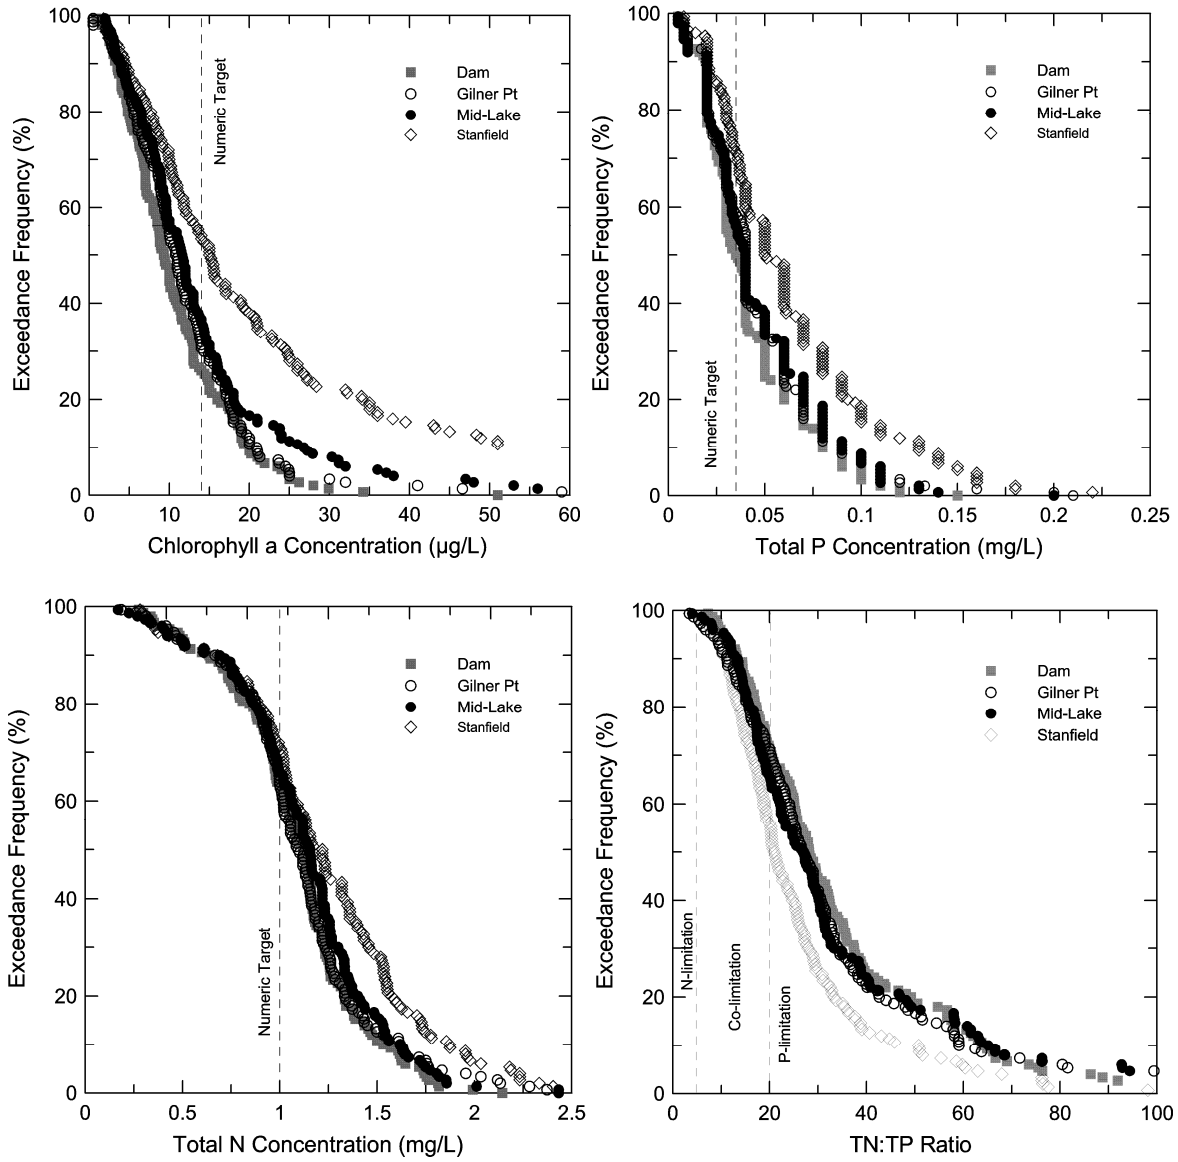

Figure 3. Cumulative distribution functions for a) chlorophyll-a, b) total P, c) total N and d) TN:TP ratios for the 4 TMDL sampling stations.

Correlations between chlorophyll-a concentrations and selected water column properties indicate that no single property captures a substantial amount of the variance in observed chlorophyll-a concentration for all four sampling stations, although the Stanfield station was somewhat more responsive to nutrient concentrations than the other stations (Table 4). Interestingly, TP concentration captured a smaller fraction of observed chlorophyll-a variance than TN (0.08-0.31 vs 0.22-0.53, respectively). Depth below full pool appears to be a useful attribute that integrates across a number of lake conditions and captured, on average, slightly more of the variance (larger R^2) in chlorophyll-a concentrations across all sites (R^2 = 0.22) compared with TP (R^2=0.21) (Table 4). Multiple linear regression using all of these parameters yielded limited improvements in R^2 values compared with single values, indicating that a substantial amount of variance in chlorophyll-a concentration is unaccounted for using basic water quality (and lake level) information (Table 4). Results are very similar when considering only summer months (Jun-Sep) (data not shown). In general, there was no strong correlation between chlorophyll-a and the parameters evaluated.

Table 4. R^2-values for correlations between selected water column properties and chlorophyll-a concentrations (Zrel full represents depth below full pool) (n=150).

Station	**TN**	**TP**	**TIN**	**TDS**	**$Z_{rel\ full}$**	**All**
Dam	0.22	0.08	0.05	0.17	0.29	0.31
Gilner Pt	0.31	0.19	0.00	0.25	0.32	0.43
Mid-Lake	0.34	0.21	0.00	0.19	0.25	0.40
Stanfield	0.53	0.31	0.04	0.18	0.22	0.55

Plots for Gilner Point highlight the variability in chlorophyll-a concentrations as a function of TP, TN, and TDS concentrations and depth below full pool ($Z_{ref\ full}$) across the wide ranging conditions present in the Lake over the 2009-2019 period (Figure 4).

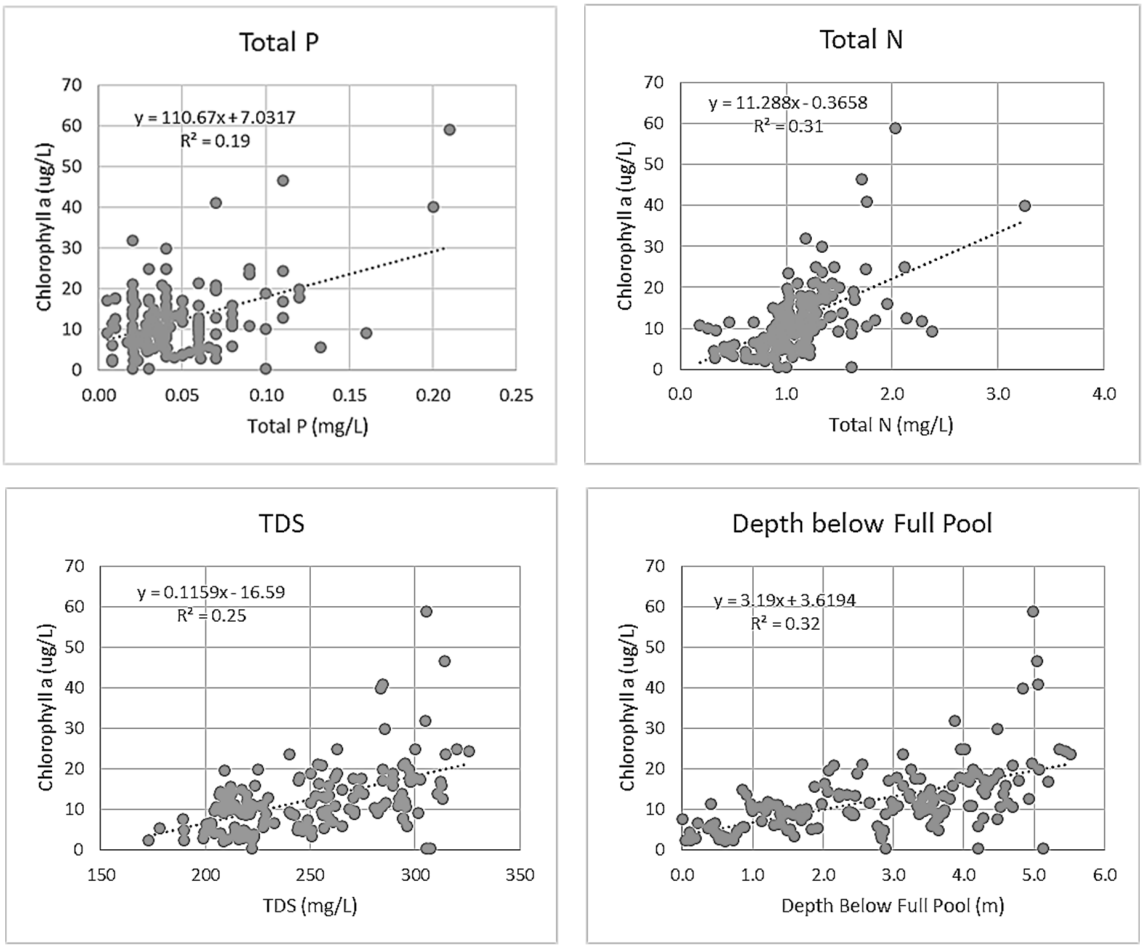

Figure 4. Plots and regression lines between chlorophyll-a and a) total P, b) total N, c) TDS and d) depth below full pool (TMDL station #2, Gilner Point).

2. Machine Learning

Linear regression equations reflected general trends indicating increases in chlorophyll-a in response to increased concentrations of nutrients, TDS, and decreasing lake level, but only captured a relatively small proportion of the variability in measured chlorophyll-a concentrations. Machine learning is often able to more effectively elucidate trends in complex datasets. Random forest and gradient boosted regression trees, k-nearest neighbor, and neural net models were developed using Python 3.7 scikit-learn (e.g., Mueller and Guido, 2017). The machine learning algorithms were trained on the 10-yr record from 2009-2018 (inclusive) and then used to predict water quality for 2019 for comparison with observed conditions.

Chlorophyll-a was the target variable in the machine learning analysis since it represents the key response variable for water quality in the Lake. Independent variables ("features") evaluated included total and dissolved N and P concentrations, water temperature, day of year, lake level

(depth below full pool), TDS concentration, and wind speed (U_w). Model goodness-of-fit was determined based on mean absolute error (MAE) and variance captured. Interestingly, nutrient concentrations and water temperature contained less value in predicting chlorophyll-a concentrations than day of year, lake level, TDS, and average wind speed. The relationships between these features and chlorophyll-a concentration at TMDL Station #1 (dam) in the training data are graphically represented in Figure 5.

The lowest set of panels in the following matrix diagram are scatter plots of chlorophyll-a (Chl) as a function of day of the year (Day), lake level below full pool (Level), TDS, and average windspeed (Uw). Visually one notes that chlorophyll-a exhibits trends of increased concentrations with increasing depth below full pool and increased TDS, although extremely large variability in chlorophyll-a concentrations exists at any given value of lake level or TDS. The final panel on the lower right side of the figure represents a frequency histogram, illustrating that most chlorophyll-a values were around 5-10 µg/L (*i.e.*, below the TMDL target of 14 µg/L), with very few observations at this station >25 µg/L (Figure 5).

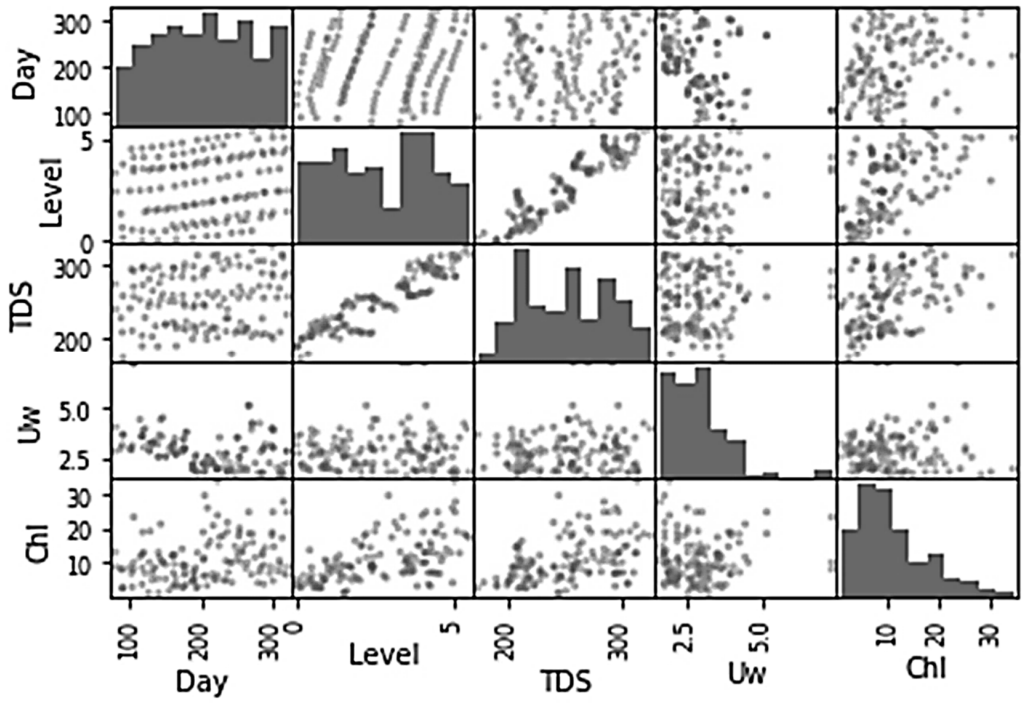

Figure 5. Matrix diagram showing scatter plots between selected parameters at TMDL station #1 (dam).

Application of the random forest regressor (RFR) and gradient-boosted regressor (GBR) using Day-Level-TDS-Windspeed as features yielded models that much more accurately reproduced observed chlorophyll-a concentrations and captured more than 90% of the variance (Figure 6, Table 5). Multiple linear regression using an expanded parameter set yielded a model that was

only better than the multi-layer perceptron (MLP) model, which actually generated excess variance.

Table 5. Mean absolute error between predicted and observed chlorophyll-a concentration and variance captured by machine learning and multiple linear regression models (2009-2018 training set).

Model (TMDL station #1)	**MAE (µg/L)**	**Variance Captured**
K-Nearest Neighbor (KNR)	3.4	0.52
Random Forest Regressor (RFR)	1.4	0.92
Gradient-Boosted Regressor (GBR)	1.0	0.96
Multi-Layer Perceptron (MLP)	14.8	-3.2
Multiple Linear Regression	3.3	0.43

The RFR and GBR models captured >90% of the variance in observed chlorophyll-a concentrations without incorporation of nutrient data (using only Day-Level-TDS-Uw), and mean absolute error (MAE) values were only about 30-40% that of the multiple linear regression model (Table 6).

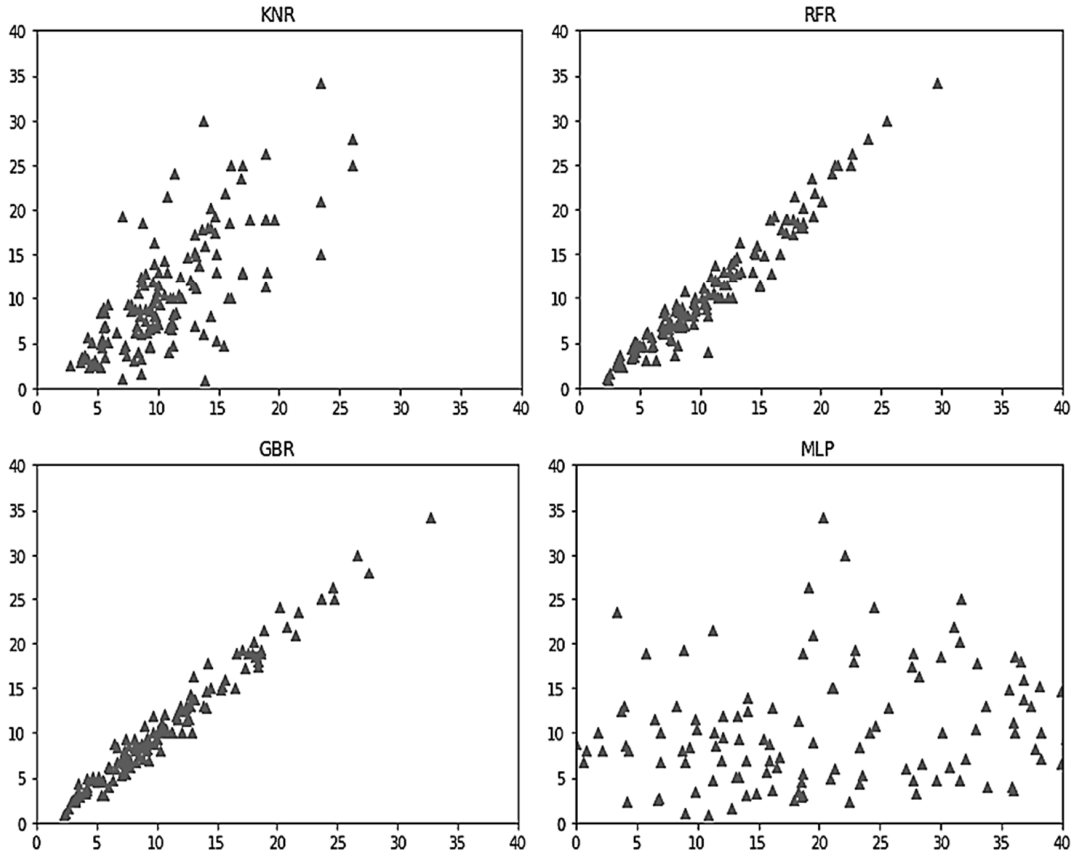

Figure 6. Scatter plots comparing predicted (x-axis) and observed (y-axis) chlorophyll-a concentrations using a) k-nearest neighbor regressor (KNR), b) random forest regressor (RFR), c) gradient-boosted regressor (GBR), and d) multi-layer perceptron (MLP) algorithms.

The RFR and GBR models had significant predictive power for 2019, capturing 58% and 73% of the variance in observed chlorophyll-a (compared with only 36% for the multiple linear regression model), although MAE values were much higher than the 2009-2018 training set. (For reference, a temperature-nutrient model captured <10% of variance in observed chlorophyll-a, underscoring the complex relationships governing algal productivity in the Lake.)

Table 6. Mean absolute error between predicted and observed chlorophyll-a concentrations and variance captured by machine learning and multiple linear regression models (2019 validation set).

Model (TMDL #1)	MAE (µg/L)	Variance Captured
Random Forest Regressor (RFR)	4.5	0.58
Gradient-Boosted Regressor (GBR)	5.9	0.73
Multiple Linear Regression	6.3	0.36

B. Internal Recycling and Hypolimnetic Mass Balance

Internal nutrient recycling is recognized as an important part of the nutrient budget of the Lake (Santa Ana Water Board, 2005). Ortho-phosphate-P (PO_4-P), sometimes also referred to as soluble reactive P (SRP), is released from bottom sediments via reductive dissolution of ferric iron-bound phosphate phases under anoxic conditions and through microbially-mediated dephosphorylation of organic matter. Similarly, NH_4-N is released from bottom sediments by deamination of organic matter. Under stratified conditions, PO_4-P and NH_4-N accumulate in the hypolimnion and their increase in concentrations allows calculation of *in situ* recycling rates.

Station #1 nearest the dam is the deepest of the four main sampling stations and is often observed to exhibit some thermal stratification during the spring through early-mid summer. One consequence of the development of thermal stratification is that nutrients released from sediments accumulate in the bottom waters and their concentrations increase over time, with NH_4-N and PO_4-P reaching, *e.g.,* up to 0.8 mg/L and 0.2 mg/L in the summer of 2010 (Figure 7).

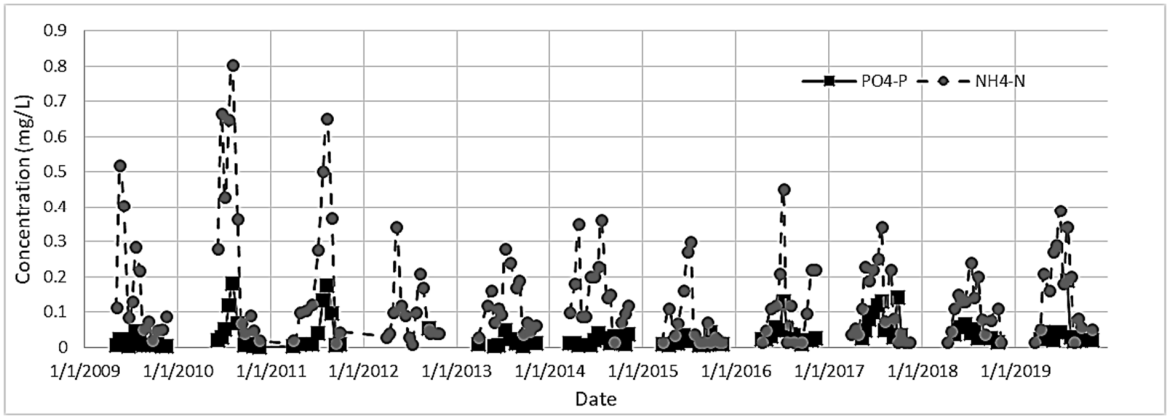

Figure 7. Concentrations of PO4-P and NH4-N in bottom water samples at TMDL station #1 (dam).

The concentrations in bottom waters tracked quite closely the magnitude of stratification, represented by △T (the difference in temperature between the 1 m and bottom depths) (e.g., Figure 8). That is, concentrations tended to increase with increasing △T, while mixing of the water column (△T near 0°C) was associated with sharp reductions in dissolved nutrients due to their mixing throughout the water column.

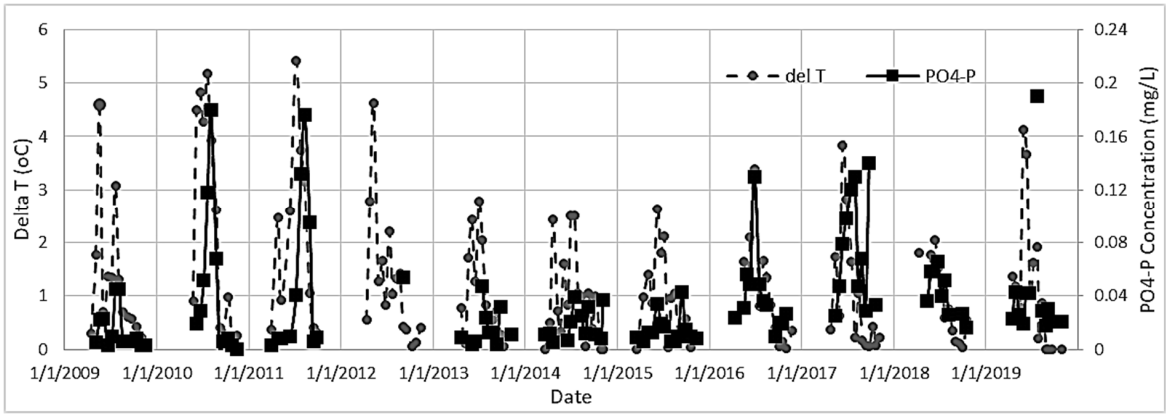

Figure 8. Relationship between bottom water PO_4-P concentrations and temperature difference between 1 m and bottom depths (△T or del T).

Stratification also results in widely-recognized loss of dissolved oxygen (DO), as aerobic bacteria consume DO; with DO unable to be replenished through exchange with the upper well-aerated mixed portion of the water column (epilimnion), oxygen demand quickly depletes DO in the hypolimnion, and is restored when the water column mixes later in the summer (Figure 9).

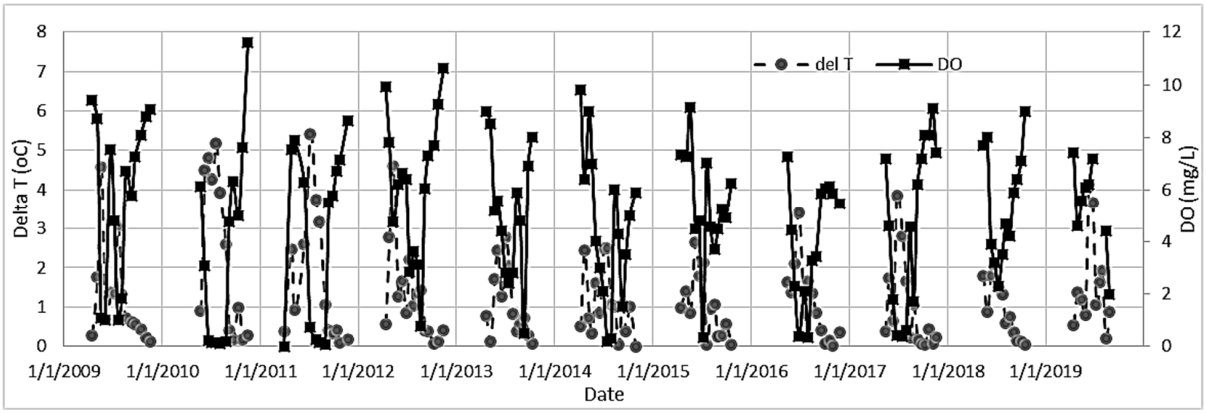

Figure 9. Relationship between bottom water DO concentrations and temperature difference between 1 m and bottom depths (△T or del T).

The increases over time in NH_4-N and PO_4-P and loss of DO (Figures 7-9) during periods of stratification (△T > 0.5 - 1°C) were used to calculate *in situ* internal recycling and areal hypolimnetic oxygen deficit (AHOD) at TMDL station #1 (Table 7). Included in this table are results from laboratory core-flux measurements in 2002-03 and following alum applications in 2004-06 and 2015 in which intact sediment cores were collected from the lake and incubated in the lab at temperature and DO conditions present at the time of sampling. Good agreement was found between 2002-03 laboratory and 2010-11 *in situ* PO_4-P flux values, while lower *in situ* values were found for NH_4-N flux. *In situ* estimates of PO_4-P flux preceding and following the 2015 alum application were in good agreement with pre- and post-laboratory core-flux incubations. AHOD

rates have not previously been measured in the Lake, so *in situ* calculations provide valuable new information about this important process. Moreover, i*n situ* AHOD values are consistent with the trophic state of the lake, and were reduced following the 2015 alum treatment. It should also be noted that similar PO_4-P and NH_4-N flux rates were measured in lab core-flux incubations following 2004 and 2015 alum treatments, indicating general reliability of alum treatments to inhibit PO_4-P release.

Table 7. Internal nutrient loading and areal hypolimnetic oxygen demand (AHOD) rates measured in laboratory and estimated from in situ hypolimnetic mass balance approach.

	Lab			*In Situ*	
Parameter	2002-03	2004-06 (post-alum)	2015 (post-alum)	2010-11	2015-17 (post-alum)
PO_4-P Flux (mg/m^2/d)	13.0 ± 2.8	3.3 ± 2.2	0.7 ± 0.2	15.9 ± 0.1	3.2 ± 1.0
NH_4-N Flux (mg/m^2/d)	92.6 ± 19.7	38.7 ± 2.7	40.3 ± 6.3	50.9 ± 10.4	26.0 ± 13.3
AHOD (g/m^2/d)	NA	NA	NA	0.46 ± 0.04	0.31 ± 0.05

Summary

To augment the water quality summaries provided in the TMDL annual reports, additional statistical and advanced machine learning analyses were conducted. Analyses focused on chlorophyll-a as the key response variable. The ratio of total N to total P), often used to identify nutrient limitation, confirm P-limitation principally in place regulating algal production. Correlations developed between total P, total N, TIN and chlorophyll-a for each of the 4 TMDL sampling stations (n=150 for each station) indicate relatively weak correlations with nutrient concentrations, so it is clear that phytoplankton levels are a more complex function of conditions in the lake. Multiple linear regression (MLR) using TN, TP, TIN, TDS and lake level yielded R^2-values of 0.31-0.55 depending upon TMDL sampling station.

Since significant portions of variance in observed chlorophyll-a concentrations remained uncaptured using MLR, machine learning was also evaluated. Random forest and gradient-boosted regressor algorithms applied to TMDL station #1 data using day of year, lake level, TDS concentration and windspeed were able to capture most (0.92-0.96) of the observed variance in chlorophyll-a for the 2009-2018 training set, notably without considering concentrations of total N or total P. For comparison, MLR using this same set of independent variables captured 0.43 of variance. The gradient-boosted regressor model also demonstrated strong forecasting power, capturing 0.73 of variance in predicted chlorophyll-a concentrations of the 2019 data set (compared with 0.36 for the equivalent MLR model). Machine learning was thus able to identify relationships and develop regressor models that reproduce and forecast concentrations with considerable accuracy.

Water column profile data were also used to quantify rates of internal nutrient recycling and AHOD. Internal nutrient recycling rates have been measured on a limited number of dates since 2002 using the laboratory core-flux method, while AHOD rates have not previously been measured at the lake. The *in situ* hypolimnetic mass balance approach using measured water

column concentrations of ammonium as N (NH_4-N) and orthophosphate as P (PO_4-P) yielded recycling rates for 2010-2011 and 2015-2017 that were similar to previously measured values confirming the importance of nutrient recycling in lake biogeochemistry and nutrient budgets, and establishing the reliability of alum treatments in suppressing PO_4-P release. The analysis also yielded *in situ* estimates of late spring-early summer AHOD rates at TMDL station #1 of approximately 0.5 $g/m^2/d$.

III. DEVELOPMENT OF 2-D HYDRODYNAMIC- WATER QUALITY MODEL FOR BIG BEAR LAKE

Numerical modeling with process-based models is routinely used to simulate historical/baseline and future conditions in lakes and reservoirs. Water quality models represent lake properties and processes through mathematical equations that can vary widely in their complexity, from simple 0-D models such as BATHTUB that involves basic mass balance calculations combined with empirical chlorophyll-a-nutrient responses (Walker, 1987), to highly complex 2-D models such as CE-QUAL-W2 (Wells, 2020) and 3-D hydrodynamic water quality models such as AEM3D (Hodges and Dallimore, 2014; Hipsey, 2014) that solve the Navier-Stokes equation and have highly complex sets of mathematical equations describing ecological interactions and water quality. Nonetheless, even with the most complex models, such models are inherently simplifications of lake ecosystems. The complexity of the model developed and its parameterization is also dependent upon the information available about the lake ecosystem. Big Bear Lake exhibits significant horizontal and vertical gradients in water quality and hydrodynamics, indicating that a 2-D laterally-averaged or 3-D representation of the lake is appropriate. Solution to the Navier-Stokes equation in 3-D is computationally extremely demanding, so 3-D hydrodynamic-water quality models are generally limited to relatively short-term simulation periods, often just months to a few years in duration, making calibration to and simulation of longer time periods often impractical. A 2-D laterally-averaged hydrodynamic-water quality model often provides sufficient resolution to capture longitudinal and vertical gradients in conditions, including local effects of inflows and outflows, while allowing for multi-year calibration of complex biogeochemical processes and simulations of decade-plus time scales.

A 2-D (longitudinal-vertical) hydrodynamic water quality model for Big Bear Lake was developed using CE-QUAL-W2 (Wells, 2018). The model was originally developed at the U.S. Army Corps of Engineers Waterways Experiment Station, extensively refined over time, and has been used for over 450 lakes and reservoirs, nearly 300 rivers, and numerous estuaries and other waterbodies (Wells, 2018). The model quantifies heat and water budgets, 2-D hydrodynamics, and predicts concentrations of nutrients, DO, chlorophyll-a, turbidity, and other parameters. The 2-D (longitudinal-vertical) representation assumes the primary gradients in water column properties and water quality are in the vertical and longitudinal directions, and well-mixed in the lateral direction; model branches can be added for embayments that allow a quasi-3-D representation of the lake. Advantages of CE-QUAL-W2 over the WASP model, which was used in early TMDL work (RWQCB, 2005), include the better spatial representation of the lake, hydrodynamic and water quality models are incorporated into a single model within CE-QUAL-W2, and it allows for multiple algal, macrophyte, and epiphyte species simulating their growth, respiration and mortality, and corresponding influence on nutrient cycling and other processes. CE-QUAL-W2 was recommended to replace the use of WASP in the 2010 TMDL Action Plan (Big Bear Lake TMDL Task Force, 2010).

A. Approach

Development and application of the model requires extensive bathymetric, hydrologic, meteorological, water quality, and other data. The model was developed focusing on the 2009-2019 time period. This period was selected based upon a number of factors, including the wide range of hydrologic and water quality conditions in the lake, and availability of extensive lake monitoring and meteorological data, as well as some watershed monitoring data. The 2-D laterally-averaged model grid was developed from the bathymetric survey data collected by Fugro Pelagos Inc. (2006), including the original dam, which was represented as an internal weir within the model. The model grid included 85 segments with 1 m vertical layers and 5 branches: branch 1, with 58 segments representing the main Lake spanning Stanfield Marsh to the Dam; and branches 2-5 representing Kidd Bay, Boulder Bay, Metcalf Bay and Grout Bay, respectively (Figure 10). Good agreement was in place between model-derived and survey-derived elevation-volume curves, with 0.36% difference in volumes at full pool (Figure 10). The model grid includes Stanfield Marsh, which was not included in original WASP simulation, and allows simulation of supplemental water through the marsh to the main lake.

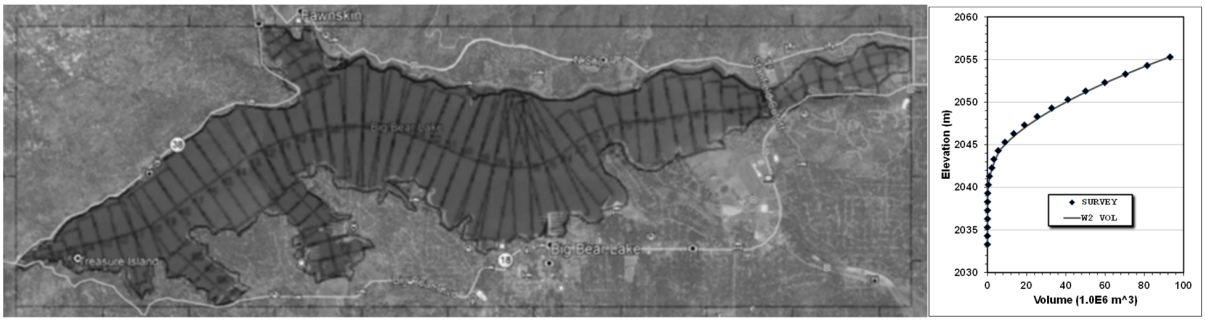

Figure 10. CE-QUAL-W2 model grid developed for Big Bear Lake. Inset depicts agreement between model and measured volume-elevation relationships.

Hydrologic data defining inflows, outflows, and withdrawals were developed from annual Water Master reports. The annual Water Master reports use measured outflows at the dam and water withdrawals by Bear Mountain Ski Resort, evaporative losses estimated using the Blaney Criddle equation, and measured lake surface elevations to derive monthly inflows to the lake. Hourly meteorological conditions were taken from Big Bear Airport and CIMIS Station #199 located at the golf course. Data included solar shortwave radiation (W/m^2), air temperature (°C), dewpoint temperature (°C), windspeed (m/s), wind direction (°) and cloud cover (%). Cloud cover was determined from sky cover conditions reported in METAR data for the airport. The model was calibrated against measured lake level, *in situ* profiles of temperature and dissolved oxygen (DO), and laboratory analyses of water samples collected at the lake.

1. Initial calibration and simulations of lake level, temperature and TDS

The initial model calibration efforts focused on reproducing observed lake levels (water balance) and water column temperatures (heat budget). Surface heat exchange was calculated term-by-term (shortwave, longwave, evaporative, and convective heat flux) with ice cover algorithm and fetch correction active. Vertical eddy viscosity was determined using the turbulent kinetic energy (TKE) formulation, with the Chezy bottom friction solution. Default heat exchange and hydraulic coefficients were generally used in simulations and are summarized in Appendix A.

Evaporation plays a dominant role in both water budget and heat budget calculations. As noted above, the Watermaster uses the Blaney Criddle equation, which is a very simple relationship that uses monthly average temperature and mean daily fraction of annual daylight hours (based on site latitude), to estimate monthly average reference evapotranspiration rate (ET_0) and evaporation rate. In contrast, CE-QUAL-W2 uses local windspeed and the vapor pressure gradient between water surface (based on water surface temperature) and overlying atmosphere (based on air temperature-relative humidity-dewpoint temperature) to determine evaporative heat and water flux on a sub-hourly basis, similar to approaches described in Chapra (2008) and Martin and McCutcheon (1999). The Blaney Criddle equation has been replaced in most applications by more sophisticated models, such as that described above for evaporation from free water surface, or the Penman-Montieth equation for reference ET_0 for estimated water demand for crops. One consequence of the use of a more accurate approach to calculating evaporation from the Lake is that inflows, which were calculated as residuals of water balance equation based upon monthly evaporation from Blaney Criddle equation, were not consistent with the improved evaporative flux rates in CE-QUAL-W2, resulting in over-estimates of water level (not shown). Thus, consistent with the Water Master approach, inflows were calculated from water balance with known lake levels, volumes and losses (with improved evaporative losses) using the CE-QUAL-W2 water balance utility. Also, as noted, the Blaney Criddle equation calculates monthly average evaporative loss, so the Water Master reports present monthly average inflows. Since weekly water surface elevation data was available, the water balance utility was able to provide finer resolution to the computed inflow data (Figure 11a). Outflow and seasonal withdrawals by the ski resort were used as reported in the Water Master Reports (Figure 11b). The severe storms and runoff generated in early 2011 represented the only substantial outflows from the lake beyond the in-stream flow requirements for Bear Creek downstream of the dam (Figure 11b). For initial water balance and TDS simulations, the distributed tributary approach was used. Allocations for specific creek discharges were used in water quality simulations and are described in more detail below.

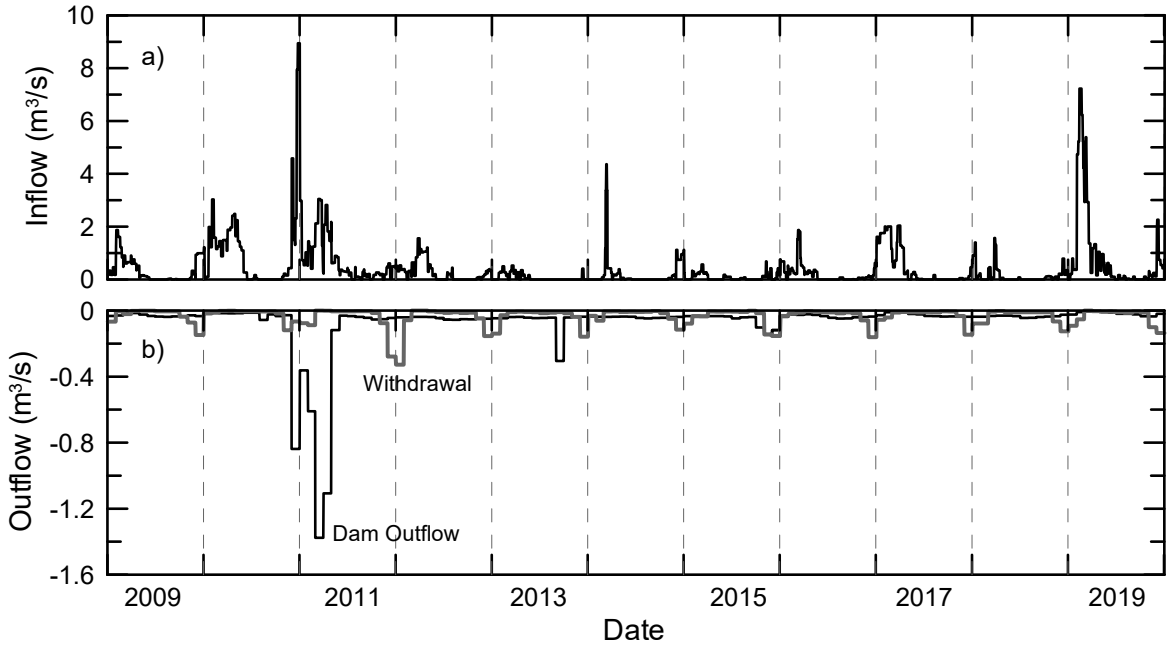

Figure 11. Hydrologic temporal boundary conditions for model calibration (2009-2019): a) total inflow and b) outflows due to withdrawals and dam outflow (from Water Master reports).

The outcome of the water balance calculations was an accurate prediction of lake level over the 2009-2019 calibration period (Figure 12). With the fitting of inflows, mean absolute error (MAE) between predicted and observed lake surface elevation was 3.6 cm.

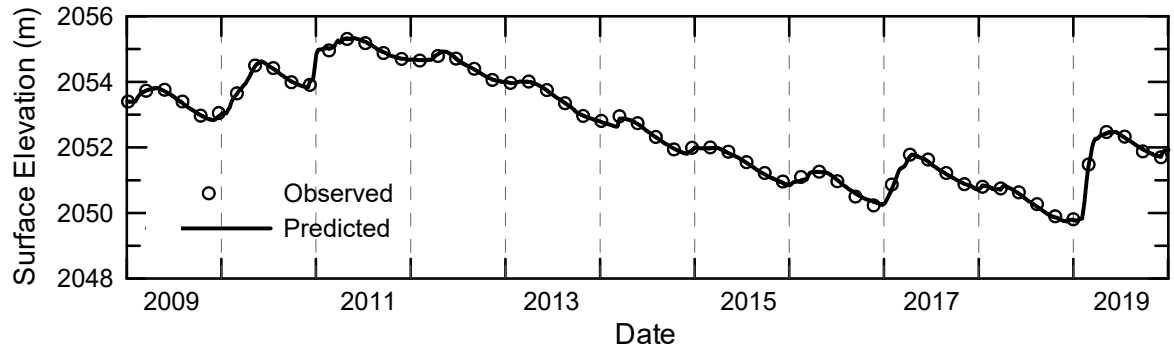

Figure 12. Predicted and observed water surface elevations.

Agreement between predicted and observed water levels is only partial confirmation of the suitability of the model for predicting water balance, since heat flux associated with evaporation is also a key component of the heat budget of lakes (Martin and McCutcheon, 1999). That is, water budgets and heat budgets are explicitly linked through the specific heat of vaporization of water. This is especially important for Big Bear Lake, where evaporation represents the principal mechanism for water loss from the lake (Santa Ana Water Board, 2005). The model quite

accurately reproduced temperature profiles in the lake (Figure 13). (Additional profile calibration figures are provided in Appendix B.)

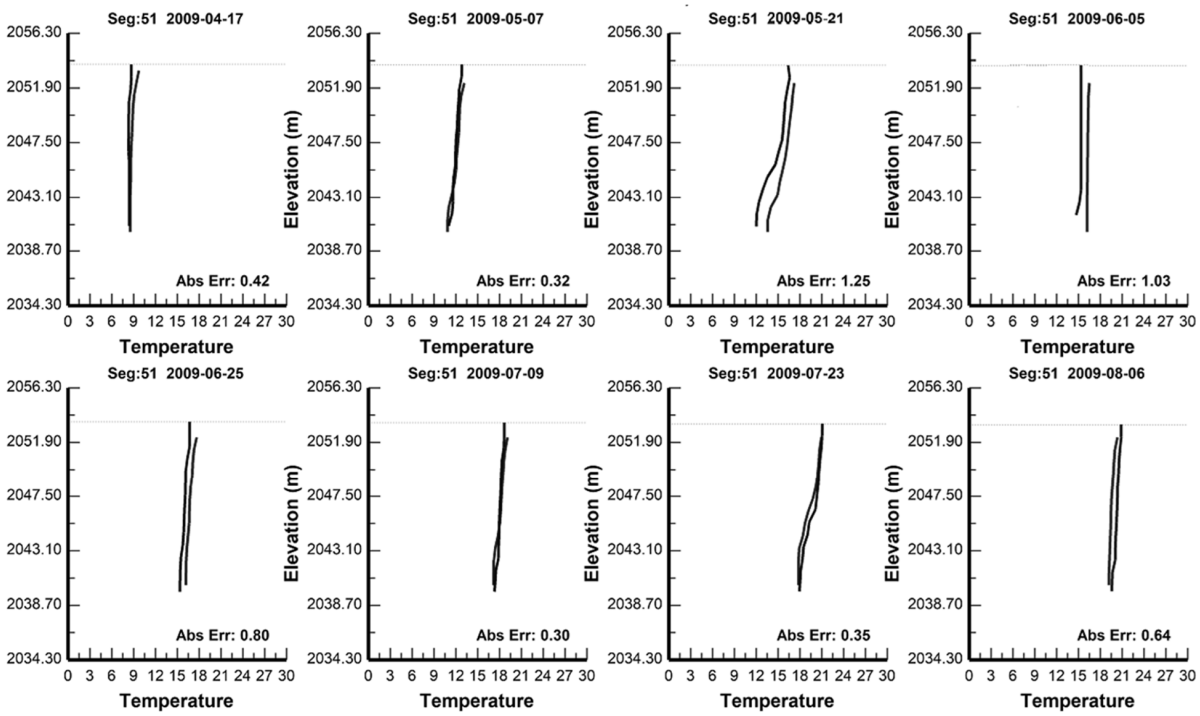

Figure 13. Model predicted and observed water column temperature profiles at station #1 (April 17 – August 6, 2009).

Mean absolute error (MAE) for temperature for profiles collected at the four TMDL sampling stations ranged from 0.95 – 1.14 °C (145 profiles, with 858-1974 discrete temperature measurements depending upon station) (Table 8).

Table 8. Mean absolute error for model predictions of water column temperatures at the four TMDL sampling stations (145 profiles; 858-1974 discrete measurements in each profile).

	#1 (Dam)	#2 (Gilner Pt)	#6 (Mid-lake)	#9 (Stanfield)
MAE (°C)	1.14	0.99	0.95	1.02

TDS concentrations were also simulated in the preliminary phase of model development and calibration. TDS concentration (g/L) was calculated from *in situ* specific conductance (mS/cm) in profile measurements with a proportionality constant of 0.65. Information about TDS (conductivity) of inflowing water was available only for very limited points in time, generally under low-moderate flow conditions. It was thus not feasible to develop comprehensive discharge-TDS relationships from available data. As an alternative, a general form of the discharge-TDS relation (inverse power law) developed from USGS gage #10260500 at Deep Creek was fitted to the Big Bear watershed of the form:

$$TDS\ (mg/L) = 36 * Q\ (m^3/s)^{-0.26} \qquad (1)$$

where Q represents the total flow to the lake derived from water budget calculations described previously. The relationship yielded a MAE of 13.3 mg/L (relative error of 15.4%) when applied to Metcalf and Summit Creek data.

Application of the TDS-flow equation to lake inflows, and simulation with CE-QUAL-W2 captured main features and trends in measured lake TDS (from conductivity) for 2009-19 (Figure 14). The MAE between predicted and observed lake TDS concentrations was 11.9 mg/L (4.8% relative error).

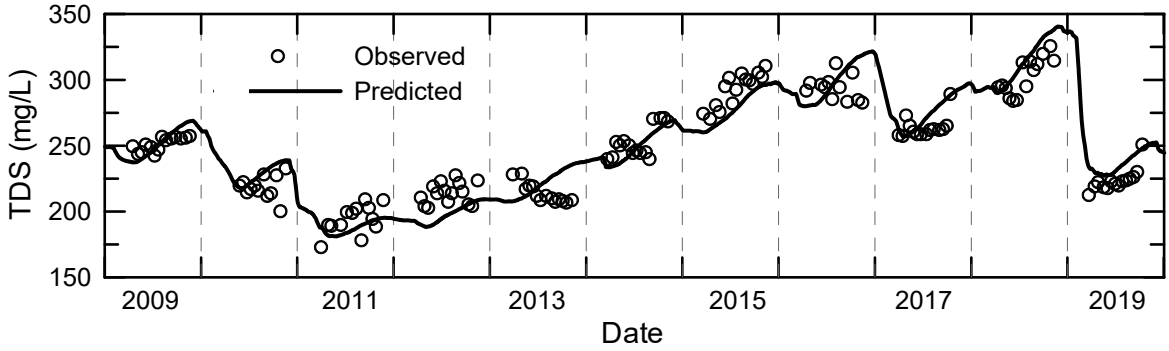

Figure 14. Predicted and observed TDS concentrations.

With the model reasonably representing lake level, water column temperature and TDS concentrations over the wide range of conditions present during 2009-2019, attention was then turned to water quality, focusing on nutrient and chlorophyll-a concentrations.

2. Calibration to Water Quality Data for Big Bear Lake

Lakes are recognized as complex ecosystems influenced by complicated physical, chemical, and biological properties, processes, and inter-relationships. Through the well-designed and high quality lake monitoring program conducted in support of the TMDL at Big Bear Lake, an excellent record of water column conditions and water quality is available with which to calibrate the CE-QUAL-W2 model. Watershed sampling has also been incorporated into the monitoring program, thus providing more extensive empirical information about nutrient and sediment contributions to the lake that were not available in earlier work, which chiefly relied on HSPF simulations of watershed runoff and loading to the lake.

As thoroughly described in the TMDL staff report, loading of nutrients to Big Bear Lake is from (i) external loading from point and nonpoint sources within the watershed, (ii) atmospheric deposition, (ii) internal recycling from bottom sediments, and (iv) macrophyte growth, senescence and death (Santa Ana Water Board, 2005). These processes were integral to the development and application of the CE-QUAL-W2 model for the lake, and are discussed in some detail below.

(i) External loading from the watershed

External loading (EL) (kg/d) from the watershed is the product of inflow rate Q_i (m^3/d) and influent concentrations C_i (kg/m^3) for each source i:

$$EL = \sum_{i=1}^{n} Q_i \, C_i \qquad (2)$$

Runoff rates from specific source areas were derived in previous modeling from HSPF simulations (Figure 15) and linked to WASP model segmentation, which excluded Stanfield Marsh (Figure 16) (Tetra Tech, 2004).

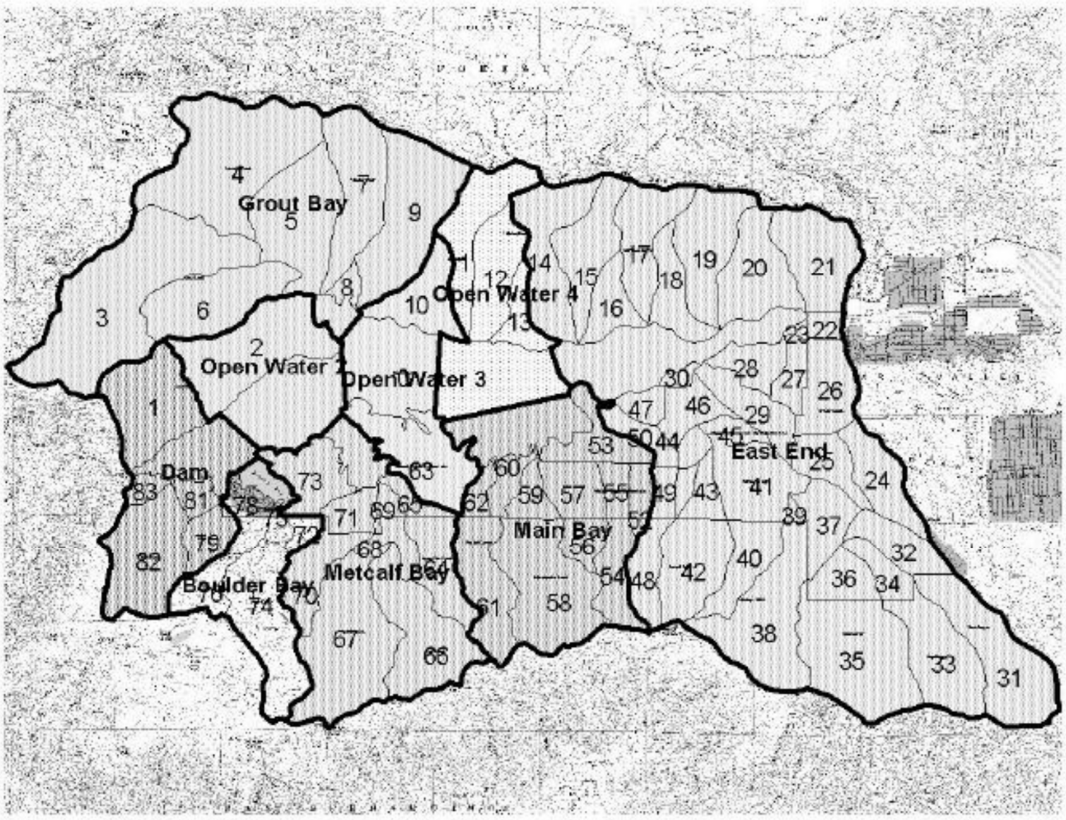

Figure 15. Contributing watershed areas to WASP segments developed from HSPF watershed model (Tetra Tech, 2004).

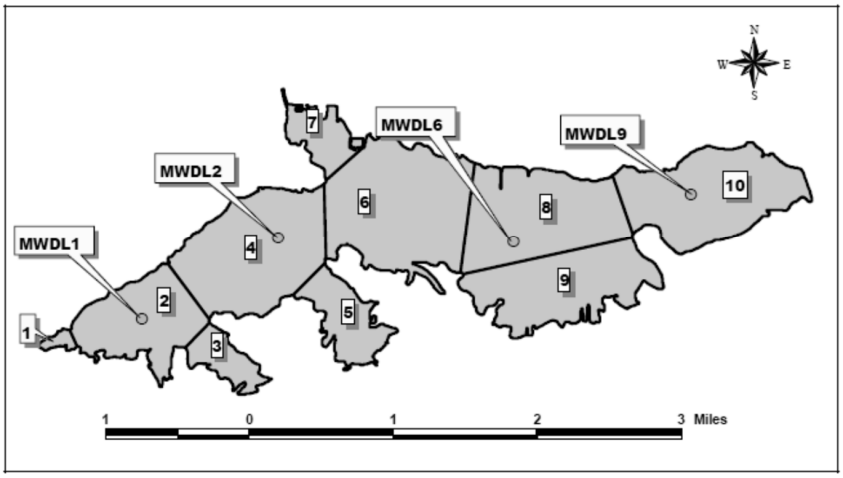

Figure 16. Model segmentation in previous WASP model simulations (Tetra Tech, 2004).

Total inflows, derived from water balance calculations described above, were allocated to regions of the lake following the approach used in the original WASP model. Total inflows (Figure 11a) were allocated to Boulder Bay, Metcalf Bay, Grout Bay and Rathbun Creek (Figure 17), based upon median % flows from prior HSPF simulation results. One difference with the earlier HSPF-WASP model approach is that the WASP model included flows to WASP segment 9 (Figure 16) as a distinct input; the coarse level segmentation in WASP does not map onto the 2-D laterally averaged grid of the CE-QUAL-W2 model, so distributed flow was used to represent both flows to segment 9 and from additional non-point sources (e.g., WASP segments 8 and 4 on the north side of the lake) (Figure 17). Distributed and Rathbun Creek flows in the CE-QUAL-W2 model collectively comprised over 65% of the total inflows to the lake.

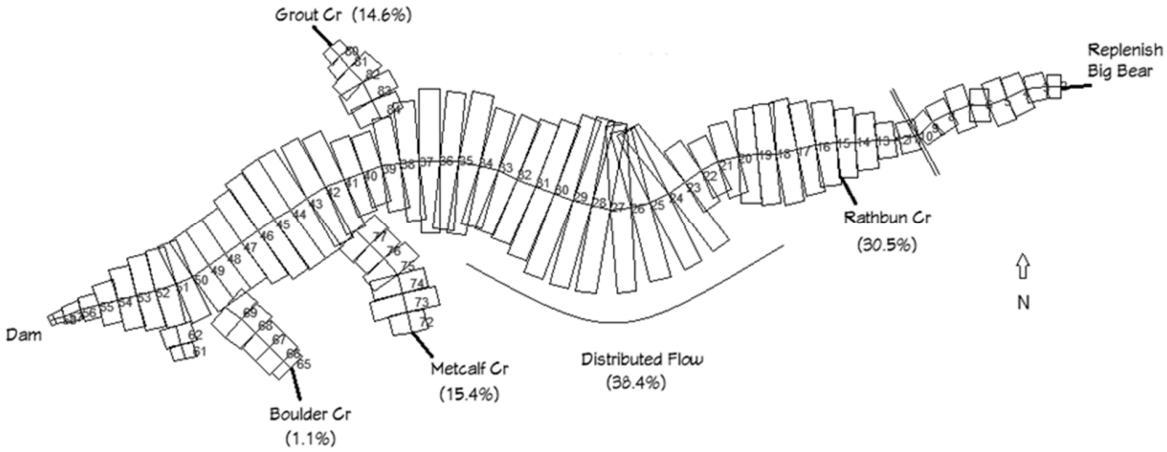

Figure 17. CE-QUAL-W2 model segmentation showing branch, tributary and distributed inflows.

Concentrations of nutrients within these different inflows over time were determined from available watershed monitoring data, rather than HSPF simulations as done in the initial WASP

model (More recent HSPF simulations have apparently been conducted, but results were unavailable.) Median concentrations based upon available data are provided in Table 9, while concentration ranges are presented in Table 10. A very limited set of measurements were identified for Boulder Creek and Grout Creek based on sampling in 2010-2011 (n=7 and 12, respectively). More extensive sampling was conducted for Knickerbocker, Rathbun, and Summit Creeks over 2010-2011 and 2016-2019 (n=53, 28 and 27, respectively). Although complete laboratory analyses on all samples were not always available. For example, laboratory measurements of total Kjeldahl N (TKN), dissolved Kjeldahl N (DKN), total organic carbon (TOC) and dissolved organic carbon (DOC) were only available for samples collected since 2016.

Table 9. Median concentrations (mg/L) of nutrients and organic C in creek water samples.

Creek	**TP**	**o-P**	**TN**	**TKN**	**DKN**	**NH_4-N**	**NO_3-N**	**TOC**	**DOC**
Boulder (n=7)	0.009	0.007	0.184	-	-	0.011	0.022	-	-
Grout (n=12)	0.024	0.015	0.282	-	-	0.008	0.121	-	-
Knickerbocker(n=53)	0.055	0.038	0.374	0.34	0.22	0.130	0.130	2.9	2.7
Rathbun (n=28)	0.055	0.038	0.786	0.46	0.36	0.419	0.419	5.1	4.9
Summit (n=27	0.069	0.021	0.530	0.52	0.25	0.180	0.180	6.0	3.6

Concentrations of total and dissolved forms of N and P varied widely, often by an order of magnitude or more, within the sampling conducted at the creeks (Table 8).

Table 10. Range in concentrations (mg/L) of nutrients and organic C in creek water samples.

Creek	**TP**	**o-PO_4-P**	**TN**	**NH_4-N**	**NO_3-N**
Boulder	0.005 - 0.017	0.005 - 0.009	0.130 - 1.103	0.007 - 0.040	0.002 - 0.042

Table 10 (contd). TOC and DOC values not reported for Boulder or Grout Creek.

Creek	**TKN**	**DKN**	**TOC**	**DOC**
Knickerbocker	0.12 - 1.20	0.012 - 0.67	1.3 - 12.0	1.4 - 8.8
Rathbun	0.077 - 1.40	0.21 - 0.77	2.9 - 7.7	2.6 - 7.1
Summit	0.10 - 0.95	0.00 - 0.78	2.8 - 7.5	2.2 - 7.0

Water quality in runoff can vary strongly depending upon characteristics of the basin, including land use, land cover, amount of impervious surfaces and other factors, and are reflected in the higher concentrations of nutrients in Knickerbocker, Rathbun, and Summit Creeks compared with Boulder and Grout Creeks (Tables 9, 10). The nature and intensity of storms (rain, snow, rain-on-snow), meteorological, and antecedent watershed conditions influence discharge and also influence water quality, contributing to the wide range in concentrations observed at the creeks (Table 10). Since a very limited number of point estimates of flow were available, it was not feasible to develop reach-specific discharge-water quality relationships, but total flows to the lake were known from water balance considerations. Measured nutrient concentration were statistically evaluated for possible correlations with total flow rates (Table 11). Sample sizes varied by creek, with only 7 and 12 samples collected from Boulder Creek and Grout Creek, respectively, while Knickerbocker, Rathbun, and Summit Creeks were sampled 53, 28 and 27

times, respectively. Weak correlations with total flow were observed for most variables, although total flow accounted for a meaningful fraction of the total variance in NO_3-N concentrations (up to R-value of 0.62, or R^2 of 0.38, representing 38% of observed variance in NO_3-N concentration for Rathbun Creek). Nonetheless, regressions even for NO_3-N had modest predictive power (Table 11, Figure 18). Assumptions about inflows and influent concentrations were necessitated by the limited amount of data and thus represent a significant source of uncertainty in model predictions.

Table 11. Correlation coefficients between flow and constituent concentrations.

Creek	**TP**	**o-P**	**TN**	**TKN**	**DKN**	**NH_4-N**	**NO_3-N**	**TOC**	**DOC**
Boulder	0.41	0.31	-0.13	-	-	0.29	-	-	-

Rathbun	-0.21	-0.20	0.28	0.04	0.38	-0.12	0.62	0.43	0.53
Summit	-0.05	0.04	0.08	0.21	0.66	-0.02	0.52	0.18	0.38

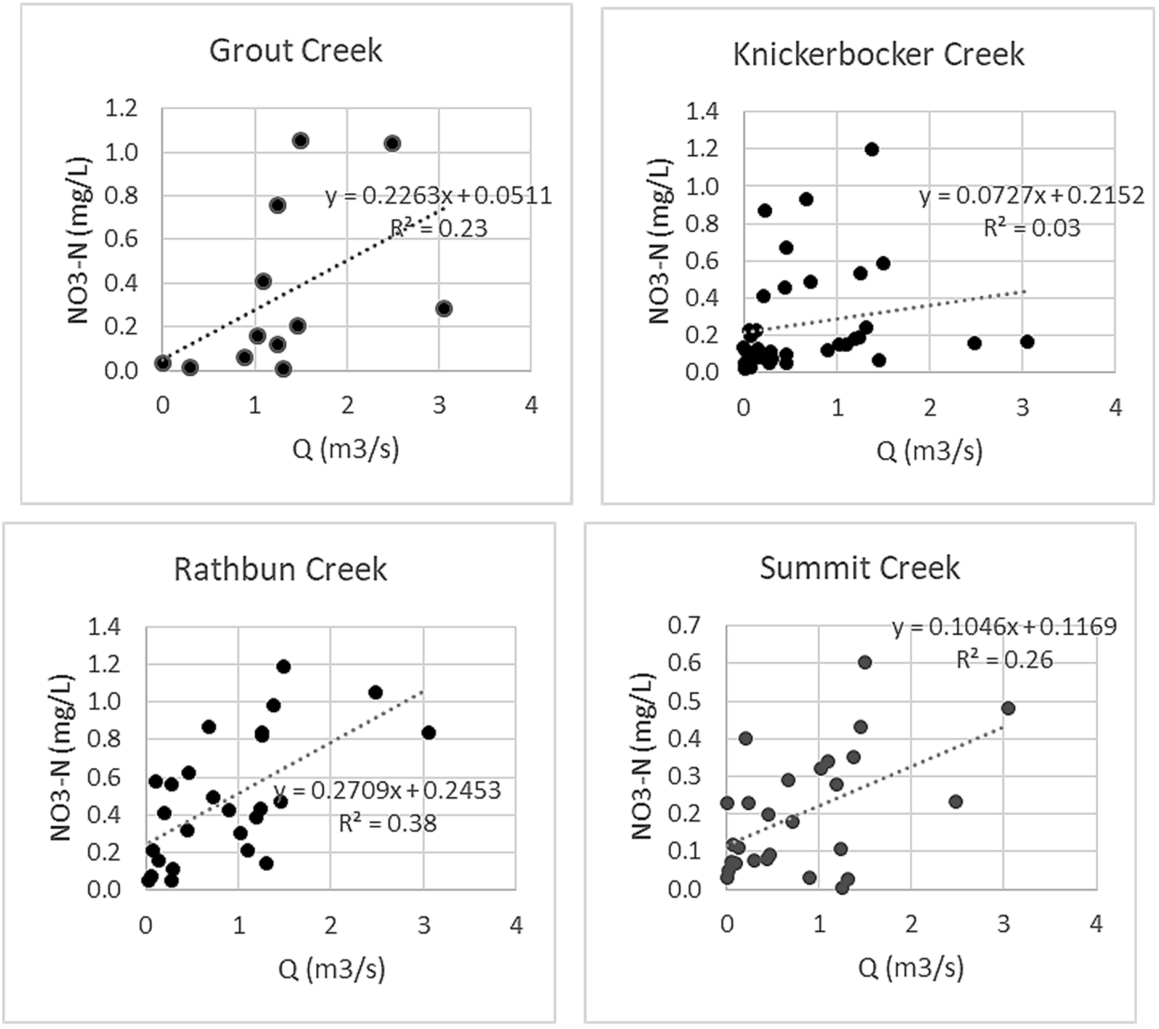

Figure 18. Plots and regression lines between NO3-N concentrations and total (lakewide) flow for a) Grout Creek, b) Knickerbocker Creek, c) Rathbun Creek, and d) Summit Creek.

Measured nitrogen and phosphorus concentrations were used when available and assumed to represent influent concentrations for the entire month in which the measurements were made; for time periods when measured values were not available, median values were used, except as follows: NO_3-N (all creeks except Boulder) and PO_4-P (Grout and Knickerbocker only), when concentrations were estimated from regressions with total flow for that date. The incorporation of measured, median, and regression-based influent concentrations into model input time-series is illustrated for Rathbun Creek (Figure 19).

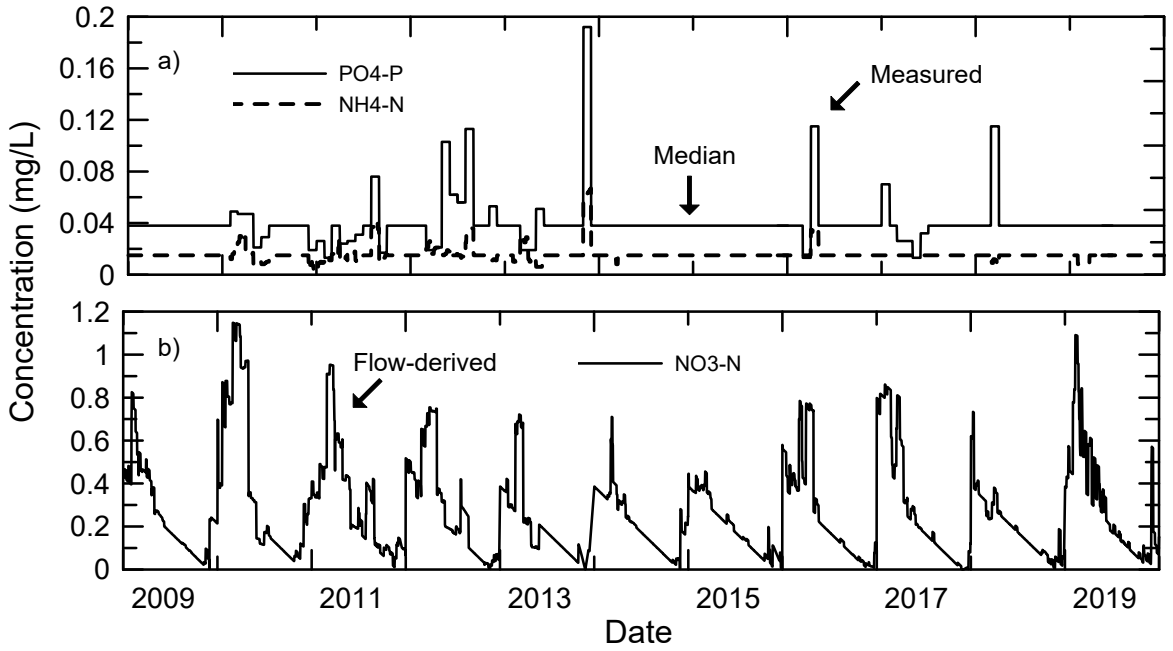

Figure 19. Modeled input nutrient concentrations in Rathbun Creek: a) PO4-P and NH4-N illustrating use of measured values when available and median values when not, and b) NO3-N concentrations derived from regression with total flow rate.

Particulate forms of N, P, and C were calculated by difference between total and dissolved forms. Following White et al. (2010) and Wetzel (1984), organic matter was further partitioned into labile and refractory forms (approximately 25 and 75%, respectively).

(ii) Atmospheric deposition

In addition to external loading from the watershed, atmospheric deposition is also an important source of N and P to Big Bear Lake. Based upon available studies by Mark Fenn and others in the San Bernardino Mountains, direct deposition of N onto the lake (assumed for modeling purposes to be equimolar NH_4 and NO_3) was estimated to be approximately 10 kg/ha/yr, while direct deposition of total P was assumed to be $1/20^{th}$ that of N, or 0.5 kg/ha/yr (Santa Ana Water Board, 2005). The CE-QUAL-W2 model does not simulate transformations and release of P bound to inorganic particles, so it was assumed that 40% of the total P (chiefly as fine inorganic dust particles) was in a bioavailable form and deposited as PO_4-P.

(iii) Internal recycling from bottom sediments

Release from bottom sediments through mineralization of organic matter and reductive dissolution of ferric oxyhydroxides was simulated in CE-QUAL-W2 using the dynamic 1^{st}-order sediment decay model combined with the 0-order SOD model. The 1^{st}-order sediment model uses a sediment compartment to accumulate organic sediments as a result of settling of algae and particulate organic matter, and allow their decay, releasing NH_4-N and PO_4-P back to the water column (Figure 20).

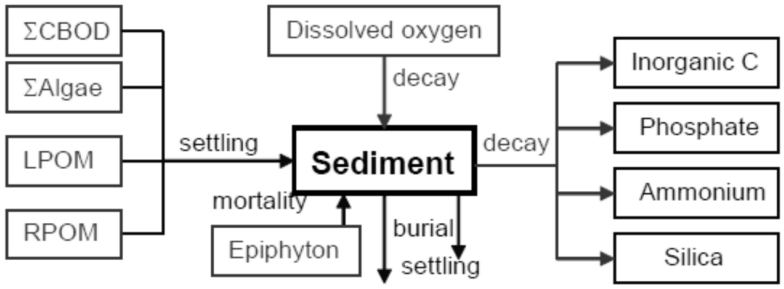

Figure 20. Schematic of 1st-order sediment subroutine in CE-QUAL-W2.

As a 1st-order process, the greater the amount of organic matter settling to the sediment compartment results in greater amounts of organic matter decayed, and N and P mineralized and released back to water column (i.e., recycled). Simulation values are provided in Table 12.

Table 12. 1st-order sediment model parameter values used in simulations. Default W2 values from Wells (2019).

Parameter	Default	Value	Description
SEDCI	0	4.4	Initial reactive sediment concentration (g/m^3)
SEDS	0.1	0.08	Sediment settling rate (m/d)
SEDK	0.1	0.1	Sediment decay rate (d^{-1})
FSOD	1	0.23	Fraction of 0-order SOD rate used
FSED	1	1	Fraction of 1st-order sediment concentration used
SEDBR	0.01	0.01	Sediment burial rate (d^{-1})

The 1st-order model simulates aerobic decomposition reactions, so sediment oxygen demand is also dynamically calculated based upon amount and type of organic matter and temperature, and depletion of DO in turn reduces rates of organic matter mineralization and deamination-dephosphorylation reactions. The 1st-order sediment model thus doesn't simulate nutrient release under anaerobic conditions, although, anaerobic decomposition and reductive dissolution reactions can be important processes within nutrient cycling. As a result, the 0-order SOD model (Figure 21) was used to simulate N and P nutrient release during anaerobic conditions. Maximum values for SOD were varied from 0.1 for shallow low organic matter sediments to 1.0 g/m^2/d at TMDL station #1 and 1.2 g/m^2/d for deepest high organic sediments adjacent to the dam; rates were assumed to vary linearly with temperature between 4 and 30°C, corresponding to a maximum summer 0-order SOD rate of about 0.6 g/m^2/d at TMDL station #1.

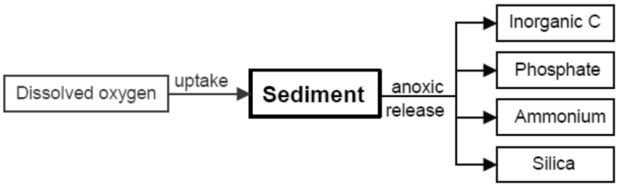

Figure 21. Schematic of 0th-order sediment oxygen demand subroutine in CE-QUAL-W2.

(iv) Macrophyte growth, senescence, and death

Macrophytes are an important component of Big Bear Lake's ecosystem, providing habitat for fish, zooplankton, larval aquatic insects, a variety of benthic animals, and epiphytic periphyton. Aquatic vegetation surveys have periodically been conducted, with coontail, common waterweed, and Eurasian watermilfoil often comprising much of the total macrophyte biomass. Macrophyte growth, senescence, and death are also important features of the nutrient cycle of the lake. Harvesting and herbicide applications have helped control macrophyte growth, with harvesting also serving as strategy to export nutrients from the lake. CE-QUAL-W2 includes macrophyte subroutines that simulate plant life cycles and their effect on hydrodynamics, nutrients, light, and other factors.

Since detailed information about the species composition, density, and distribution of macrophytes over the 2009-2019 timeframe was not available, a composite macrophyte group was incorporated into the model. CE-QUAL-W2 modeling conducted by the USGS (2013) for the Klamath River upstream of Keno Dam, Oregon served as the basis for macrophyte submodel parameterization (Table 13). The composite macrophyte extracted nutrients from the water column, as coontail and to a slightly lesser extent milfoil do, and from bottom sediments, as typical rooted aquatic vascular plants do.

Table 13. Macrophyte model parameter values used in simulations.

Parameter	USGS[a]	Value	Description
MG	0.34	0.3	Maximum macrophyte growth rate (d^{-1})
MR	0.09	0.09	Maximum macrophyte respiration rate (d^{-1})
MM	0.06	0.06	Maximum macrophyte mortality rate (d^{-1})
MSAT	5	10	Light saturation intensity at max photosynthesis rate (W/m^2)
MPOM	0.7	0.7	Fraction of macrophyte biomass converted to POM upon death
LRPMAC	0.2	0.2	Fraction of POM that becomes labile POM
PSED	0.4	0.27	Fraction of P uptake from sediments
NSED	0.4	0.27	Fraction of N uptake from sediments
MBMP	40	40	Threshold concentration when growth to next layer (g/m^3)
MMAX	108	1000	Maximum macrophyte concentration (g/m^3) (W2 default = 500 g/m^3)
CDDRAG	0	1	Macrophyte drag coefficient
MT1	14	14	Lower temperature for rising growth rate function (°C)
MT2	24	24	Upper temperature for rising growth rate function (°C)
MP	0.004	0.005	Stoichiometric ratio between P and biomass (g/g)
MN	0.054	0.05	Stoichiometric ratio between N and biomass (g/g)
MC	0.51	0.5	Stoichiometric ratio between C and biomass (g/g)

[a]composite macrophyte based on average of values for Coontail and Common Waterweed. USGS (2013).

v. Epiphyton dynamics

A vast majority of algal species can colonize surfaces, including macrophytes, and can approach or exceed primary production of macrophytes (*e.g.,* Jones, 1984). Given the relatively shallow depths in the embayments and eastern end of the lake and relatively high water clarity much of the year, epiphyton were also included in the model. Epiphyton are subject to the same

environmental factors and processes as phytoplankton with the exception of settling loss from the water column (Table 14).

Table 14. Epiphyton model parameter values used in simulations. Default W2 values from Wells (2019).

Parameter	Default	Value	Description
EG	2	2	Maximum epiphyton growth rate (d^{-1})
ER	0.04	0.045	Maximum epiphyton respiration rate (d^{-1})
EE	0.04	0.045	Maximum epiphyton excretion rate (d^{-1})
EM	0.1	0.1	Maximum epiphyton mortality rate (d^{-1})
EB	0.001	0.001	Epiphyton burial rate (d^{-1})
EHSP	0.003	0.003	Epiphyton half-saturation for P-limited growth (g/m^3)
EHSN	0.014	0.014	Epiphyton half-saturation for N-limited growth (g/m^3)
EHSSI	0	0	Epiphyton half-saturation for Si-limited growth (g/m^3)
ESAT	75	75	Light saturation intensity at max photosynthesis rate (W/m^2)
EHS	35	82	Biomass limitation factor (g/m^2)
ENEQN	2	2	Ammonia preference factor equation (1 or 2)
ENPR	0.001	0.001	N-half saturation preference constant (g/m^3)
EP	0.005	0.003	Stoichiometric ratio between P and biomass (g/g)
EN	0.08	0.082	Stoichiometric ratio between N and biomass (g/g)
EC	0.45	0.45	Stoichiometric ratio between C and biomass (g/g)

vi. Phytoplankton dynamics

With information about external nutrient loading from the watershed, atmospheric deposition, internal nutrient recycling, and role of macrophytes and epiphyton, attention was then turned to parameterization of the model to reproduce seasonal and interannual phytoplankton dynamics as expressed through trends in chlorophyll-a. Algal levels are governed by the availability of nutrients and light, and regulated by a complex set of processes, including respiration, settling, grazing, and mortality (Figure 22):

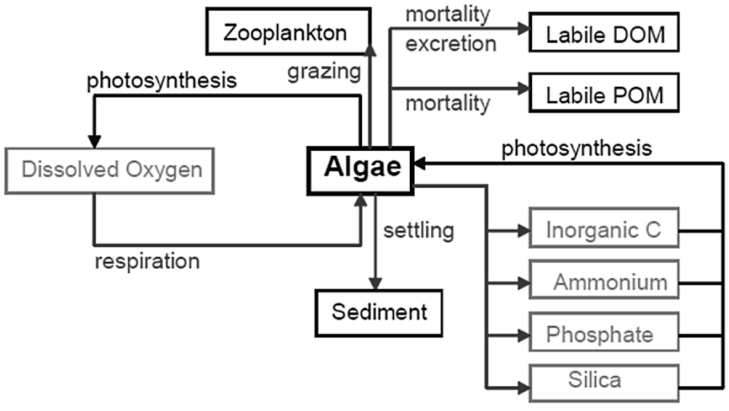

Figure 22. Schematic of phytoplankton subroutine in CE-QUAL-W2.

No specific genus or species was simulated and parameter values at or near CE-QUAL-W2 default values were used (Table 15). Two phytoplankton groups were simulated, with algal group #2 capable of N_2-fixation.

Table 15. Phytoplankton model parameter values used in simulations. Default W2 values from Wells (2019).

Parameter	Default	Algae 1	Algae 2	Description
AG	2	2	1.7	Maximum algal growth rate (d^{-1})
AR	0.04	0.04	0.05	Maximum algal respiration rate (d^{-1})
AE	0.04	0.04	0.05	Maximum algal excretion rate (d^{-1})
AM	0.1	0.1	0.1	Maximum algal mortality rate (d^{-1})
AS	0.1	0.1	0.1	Algal settling rate (d^{-1})
AHSP	0.003	0.003	0.005	Algal half-saturation for P-limited growth (g/m^3)

AEC	0.45	0.45	0.45	Stoichiometric ratio between C and biomass (g/g)

3. Model Calibration Results

As previously noted, water quality in Big Bear Lake varied widely over 2009-2019 (Table 1). The model reproduced seasonal and inter-annual variations in chlorophyll-a concentrations reasonably well, including increased concentrations in the latter half of the 2009-2019 study period associated with lower lake levels (Figure 23).

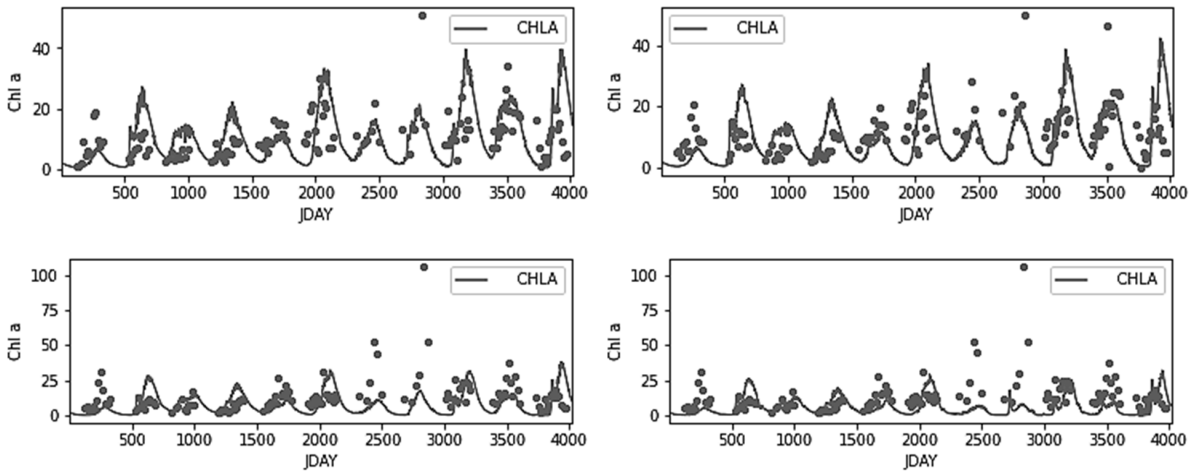

Figure 23. Predicted (line) and observed (circles) chlorophyll-a concentrations (µg/L) over 2009-2019 calibration period for TMDL sampling stations: a) #1 (dam), b) #2 (Gilner Point), c) #6 (Mid-lake), and d) #9 (Stanfield). JDAY represents simulation day (elapsed Julian day) since 1/1/2009.

The model also reproduced central tendencies present in measured TP concentrations, including seasonal variations and trends of increased concentrations in the latter half of the 2009-2019 study period, but predicted seasonal variations that were dampened relative to reported data (Figure 24). In particular, the model over-predicted total P around day 2300-2600 which corresponds to the alum application in 2015. CE-QUAL-W2 doesn't have subroutines specifically simulating an alum application, and after some effort, it was deemed not readily feasible to accurately simulate the flocculation, sorption, and settling of alum and sorbed P and N within CE-QUAL-W2. Some limitations to the macrophyte submodel were also identified (Appendix C).

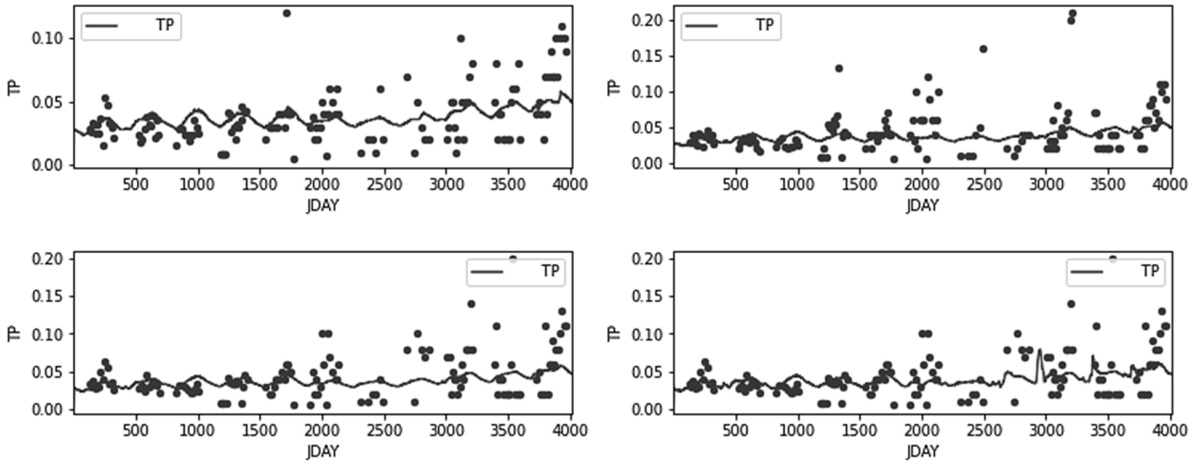

Figure 24. Predicted (line) and observed (circles) total P (TP) concentrations (mg/L) over 2009-2019 calibration period for TMDL sampling stations: a) #1 (dam), b) #2 (Gilner Point), c) #6 (Mid-lake) and d) #9 (Stanfield). JDAY represents simulation day (elapsed Julian day) since 1/1/2009.

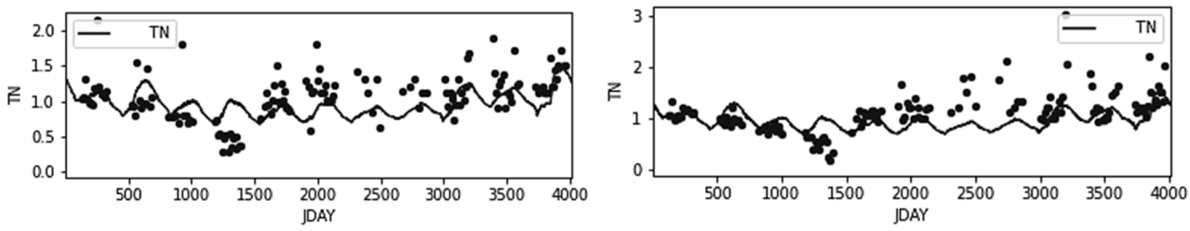
The
prec
corr
might be expected to increase N concentrations somewhat, as further P-limitation would restrict amount of N also incorporated into algal biomass.



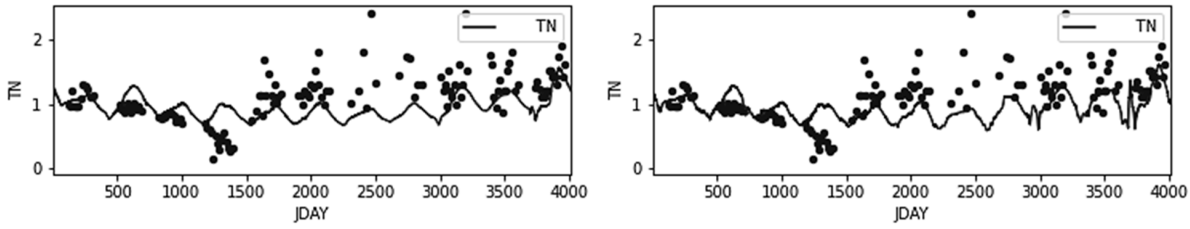


Figure 25. Predicted (line) and observed (circles) total N (TN) concentrations (mg/L) over 2009-2019 calibration period for TMDL sampling stations: a) #1 (dam), b) #2 (Gilner Point), c) #6 (Mid-lake) and d) #9 (Stanfield). JDAY represents simulation day (elapsed Julian day) since 1/1/2009.

As evident in Figures 23-25, very wide swings in reported total nutrient and chlorophyll-a concentrations were sometimes present, with sample concentrations occasionally up to 3-5 times higher than samples collected immediately prior to or immediately thereafter (e.g., Figure 24, TP concentration of 0.12 mg/L around day 1700 for TMDL station #1). While analytical error is present in all measured values, a Grubbs outlier test was used to identify outliers at $p<0.01$ prior to calculation of model error statistics. A total of 7/424 outliers were statistically identified for chlorophyll-a, 5/600 for total P, 2/600 for total N and 6/600 for total inorganic N. Outliers removed due to analytical, sample handling, or other errors thus constituted only 0.33-1.6% of total reported values. Even with removal of outliers at $p<0.01$, it nonetheless bears noting that model calibration errors have field and laboratory errors imbedded within them, as well as from other factors (Harmel et al., 2006). Model error statistics, including mean error, mean absolute error, and root mean square error, are summarized in Table 16.

Table 16. Model error results for nutrients and chlorophyll-a.

Property	N	Range	ME	MAE	RMSE	RRMSE (%)[a]
Chlorophyll-a (µg/L)	417	0.5 – 43.2	-1.3	7.9	10.3	24.0
Total P (mg/l)	595	0.005 - 0.180	-0.010	0.022	0.031	17.7
Total N (mg/L)	598	0.126 - 2.415	-0.148	0.310	0.413	18.0
Total Inorganic N (mg/L)	594	0.007 - 0.319	-0.049	0.050	0.092	29.5

[a]=(RMSE/Range)*100

Dissolved oxygen concentrations are influenced by, and also often regulate, the biogeochemical processes operating in the lake. It was previously shown that the model adequately reproduced water column temperatures (Figure 13, Table 8); the model was also generally successful in reproducing measured DO concentrations (*e.g.*, Figure 26, Table 17). (Additional profiles provided in Appendix D). While the lake was often relatively well-mixed vertically, low DO concentrations above the sediments were frequently present as a result of aerobic decomposition and respiration reactions.

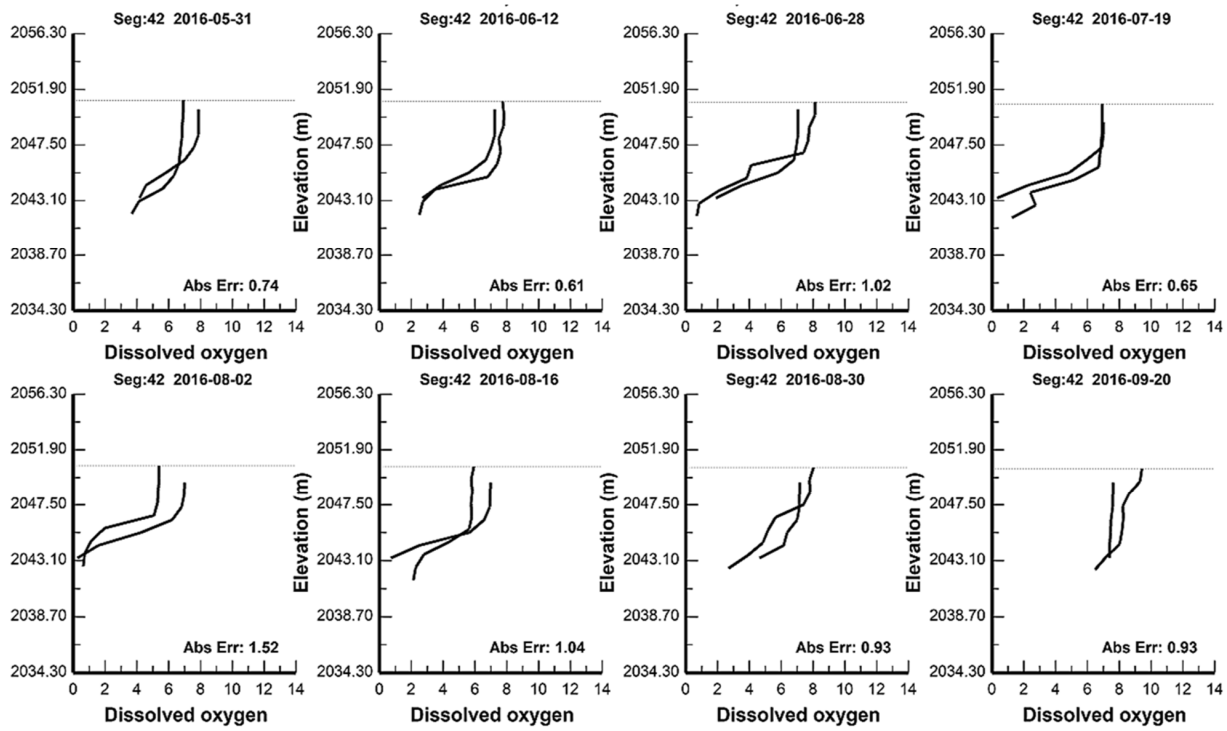

Figure 26. Example dissolved oxygen profiles at TMDL station #2 highlighting agreement between predicted and measured concentrations and periodic loss of DO in lower water column.

Table 17. Mean absolute error for model predictions of water column DO concentrations at the four TMDL sampling stations (145 profiles; 858-1974 discrete measurements in each profile).

	#1 (Dam)	#2 (Gilner Pt)	#6 (Mid-lake)	#9 (Stanfield)
MAE (mg/L)	1.40	1.25	1.16	1.02

Summary

A 2-D (longitudinal-vertical) hydrodynamic -water quality model for Big Bear Lake was developed using CE-QUAL-W2. The 2-D laterally-averaged model grid was developed from the bathymetric survey data collected by Fugro Pelagos Inc. (2006). Hydrologic data defining inflows, outflows, and withdrawals were developed from annual Big Bear Water Master reports. Hourly meteorological conditions were taken from Big Bear Airport and California Irrigation Management Information System (CIMIS) Station #199 located at the golf course. Data included solar shortwave radiation, air temperature, dewpoint temperature, windspeed, wind direction and cloud cover. Cloud cover was determined from sky cover conditions reported in METAR data for the airport. The model was calibrated against measured lake level, *in situ* profiles of temperature and DO, and laboratory analyses of water samples collected at the lake for 2009-2019. The model was first developed and calibrated for lake level, water column temperature profiles and TDS, where generally very good agreement was achieved (mean absolute errors of 3.6 cm, 0.79-0.89 °C, and 11.9 mg/L, respectively). Following this, model calibration to water quality data was conducted. The model included external nutrient loading from the watershed,

atmospheric deposition, internal nutrient recycling, and nutrient uptake and release associated with macrophyte and epiphyton growth, senescence and death. Two algal groups were simulated, included one representing cyanobacteria capable of N_2-fixation. The 1^{st}-order dynamic sediment model was combined with the 0^{th}-order SOD model to simulate nutrient recycling and DO uptake in the surficial bottom sediments. Relative root mean square error was 17.7% for total P, 18.0% for total N, 29.5% for TIN, and 24.0 % for chlorophyll-a. Mean absolute errors for DO ranged from 1.02 – 1.40 mg/L for the 4 TMDL sampling stations.

IV. APPLICATION OF MODEL TO EVALUATE CONDITIONS WITH REPLENISH BIG BEAR PROJECT

With some confidence that the model is able to reproduce trends in water quality over a wide range of conditions, the model was used to evaluate changes in lake level and water quality under selected Replenish Big Bear project treatment scenarios. For these simulations, 1,920 af of BBARWA WWTP effluent was delivered annually through Stanfield Marsh and subsequently to the Lake. Three progressive levels of treatment assuming advanced nutrient removal and reverse osmosis (RO) technologies were evaluated (Treatment Alternatives):

(i) Alternative 1: TIN & TP Removal
(ii) Alternative 2: 70% RO (70% RO + 30% TIN & TP Removal)
(iii) Alternative 3: 100% RO

The composition of the supplemental water used in simulations varied quite substantially depending upon level of treatment (Table 18).

Table 18. Water quality of supplemental water used in model simulations (WSC, 2020b).

Constituent (mg/L)	Alternative 1	Alternative 2	Alternative 3
TDS	450	150	50
NO_3-N	0.6	0.2	0.05
NH_4-N	0.2	0.1	0.05
PO_4-P	0.25	0.06	0.02
Dissolved Organic N	1.33	0.76	0.5
Dissolved Organic P	0.24	0.04	0.01
Particulate Organic N	0.07	0.04	0.00
Particulate Organic P	0.01	0.002	0.00

These three Treatment Alternatives, with varying concentrations of TDS, phosphorus, and nitrogen (Table 18), and a flow rate of 1,920 af/yr were simulated to evaluate effects of supplementation on lake levels and concentrations of TDS, nutrients and chlorophyll-a concentrations for comparisons with baseline (2009-2019) conditions. This analysis thus allows one to compare how different Replenish Big Bear Treatment Alternatives would have altered lake conditions over the past decade, which included extreme variations in lake level and water quality.

A. Lake Level

A simple water balance calculation indicates that 1,920 af/yr of water added to Big Bear Lake would add approximately 0.2 m/yr to lake level. This level of supplementation represents about a 20% increase in average total annual inflow on a calendar year basis, with substantially larger relative contributions during periods of drought (e.g., nearly doubling the very low inflow shown in Fig. 11a during 2013). Simulations confirm that supplemental water would have increased lake level substantially over the natural 2009-2019 period (Baseline scenario), up to 1.7 m by late 2018 relative to no project (Figure 27).

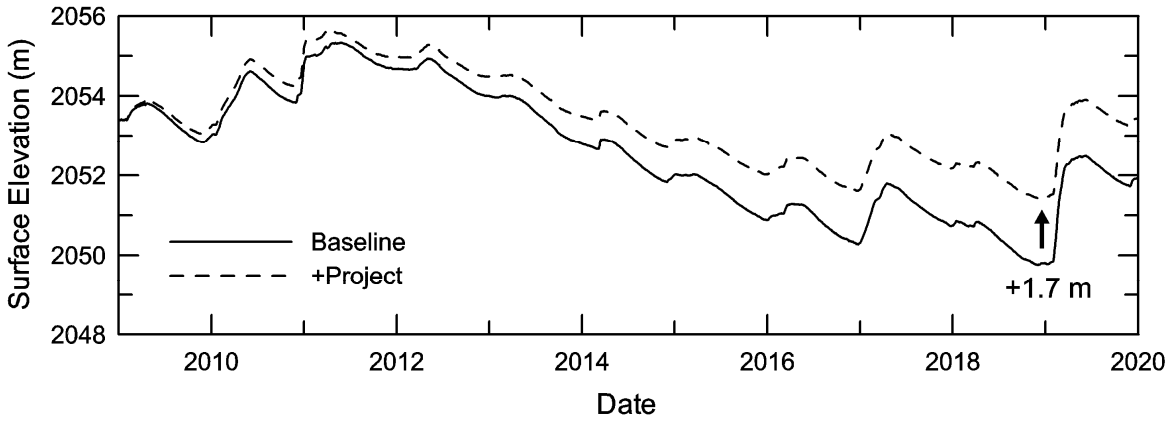

Figure 27. Predicted lake surface elevations over 2009-2019: baseline and with project.

B. Lake Area

The supplemental water also translates to increased lake surface area (Figure 28) that is a function of elevation-volume-area relationships for the Lake basin (Figure 9). Benefits of increased Lake area are especially evident during periods of drought, when Lake shoreline has substantially receded, limiting recreational and homeowner access, and resulting in extensive loss of the littoral community. For example, supplementation with project water would have increased lake area by about 300 acres, from less than 1,900 acres in 2018 to nearly 2,200 acres (Fig. 28). Moreover, the benefits of supplementation to Lake level and Lake surface area in terms of recreational access, aesthetics, ecological habitat, etc. accrue over time, especially evident during drought, until large inflows restore lake level and reset hydrologic conditions in the Lake.

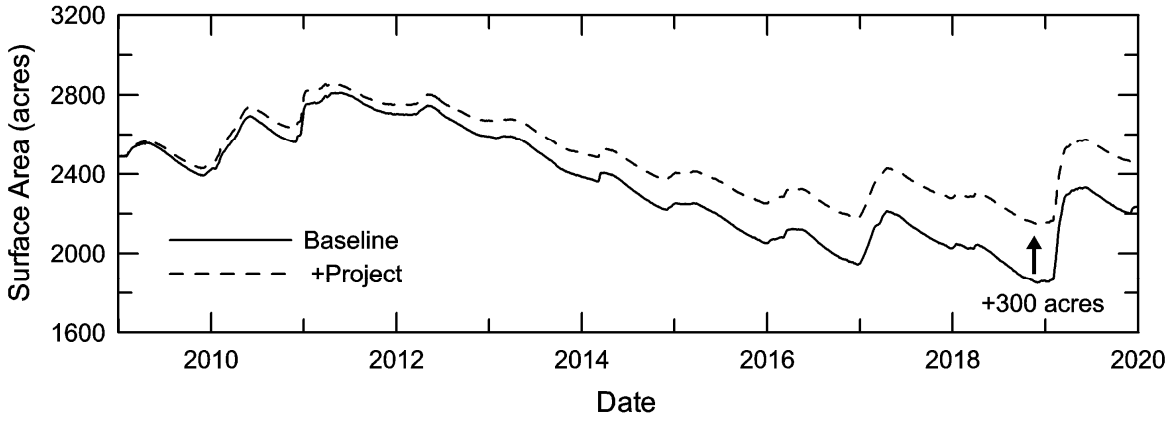

Figure 28. Predicted lake surface area over 2009-2019: baseline and with project.

C. TDS

Addition of 1,920 AFY of Alternative 1 effluent with a TDS of 450 mg/L, predictably increased TDS relative to the Baseline scenario, while Alternative 2 effluent yielded predicted TDS concentrations similar to those present in 2009-2019, and Alternative 3 effluent lowered TDS levels below the Baseline scenario (Figure 29; Table 19).

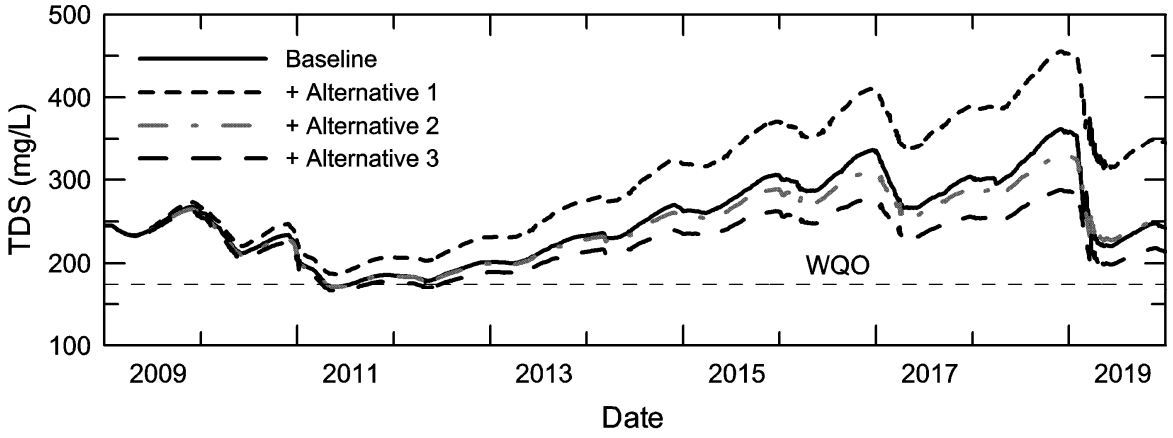

Figure 29. Predicted TDS concentrations over 2009-2019: baseline and with project.

Predicted TDS for the Baseline scenario exceeded the WQO of 175 mg/l (dashed line) 97.6% of the time over 2009-2019, a frequency equivalent to that of the Alternative 2 treatment scenario, and greater than that with Alternative 3 treatment scenario (Table 19).

Table 19. Summary of TDS concentrations for 2009-2019 under natural conditions and with project.

Scenario	Average TDS (mg/L)	Range TDS (mg/L)	WQO Exceedance Frequency (%)
Baseline	251	172-362	97.6
Alternative 1	300	187-455	100.0
Alternative 2	244	171-329	97.6
Alternative 3	226	166-287	93.3

D. Nutrients and Chlorophyll-a

Nutrients entering the lake add to the inventory of nutrients already present, which are subject to a wide array of biogeochemical processes. To help put nutrients derived from supplemental water of differing levels of treatment into context, it is useful to consider their composition and loading relative to watershed sources. Median watershed concentrations and concentrations in Alternative 1-3 effluents are provided in Table 20. Alternative 1 effluent substantially exceeds median watershed concentrations for virtually all nutrients, while addition of RO in Alternatives 2 and 3 lowers concentrations, often to levels comparable to or in some cases below median watershed levels.

Table 20. Comparison of nutrient concentrations in watershed runoff and supplemental water with the three Treatment Alternatives.

	Median Watershed Concentrations (mg/L)					Nutrient Concentrations (mg/L)		
Variable	Boulder Cr	Grout Cr	Knickerb Cr	Rathbun Cr	Summit Cr	Alt 1	Alt 2	Alt 3
NO_3-N	0.05	0.183	0.13	0.419	0.19	0.6	0.2	0.05
NH_4-N	0.011	0.01	0.015	0.015	0.015	0.2	0.1	0.05
PO_4-P	0.007	0.015	0.038	0.038	0.021	0.25	0.06	0.02
Total N	0.184	0.378	0.312	0.716	0.481	2.2	1.1	0.6
Total P	0.009	0.023	0.055	0.055	0.075	0.5	0.1	0.03
TN/TP	20.4	16.4	5.7	13.0	6.4	4.4	11	20

Normalizing project concentrations as ratios to median watershed concentrations allows comparison of relative enrichment factors for supplemental water (concentration basis) (Table 21):

Table 21. Concentration enrichment factors (supplemental/watershed).

	Concentration Enrichment Factor		
Variable	Alternative 1	Alternative 2	Alternative 3
NO_3-N	3.3	1.1	0.3
NH_4-N	13.3	6.7	3.3
PO_4-P	11.9	1.6	0.5
Total N	5.8	2.3	0.8
Total P	9.1	1.8	0.4

One thus recognizes that Alternative 1 (TIN & TP Removal) effluent represents about 6-times and 9-times greater concentrations of TN and TP, respectively, compared with the watershed, while Alternative 2 (70% RO) is on the order of about 1-2 times higher concentrations, and Alternative 3 (100% RO) is significantly lower than typical concentrations of most forms of nutrients delivered from the watershed (Table 21). Importantly, Alternative 1 effluent is not only much higher in nutrient concentrations, it also has a very low TN:TP ratio (Table 20), that could potentially favor N_2-fixing blue-green algae.

Simulations demonstrated that water quality in the Lake is broadly similar between the Baseline scenario and the Alternative 2 and 3 treatment scenarios, but is significantly degraded with Alternative 1 effluent, with marked predicted increases in TP, TN, and chlorophyll-a concentrations (Figure 30).

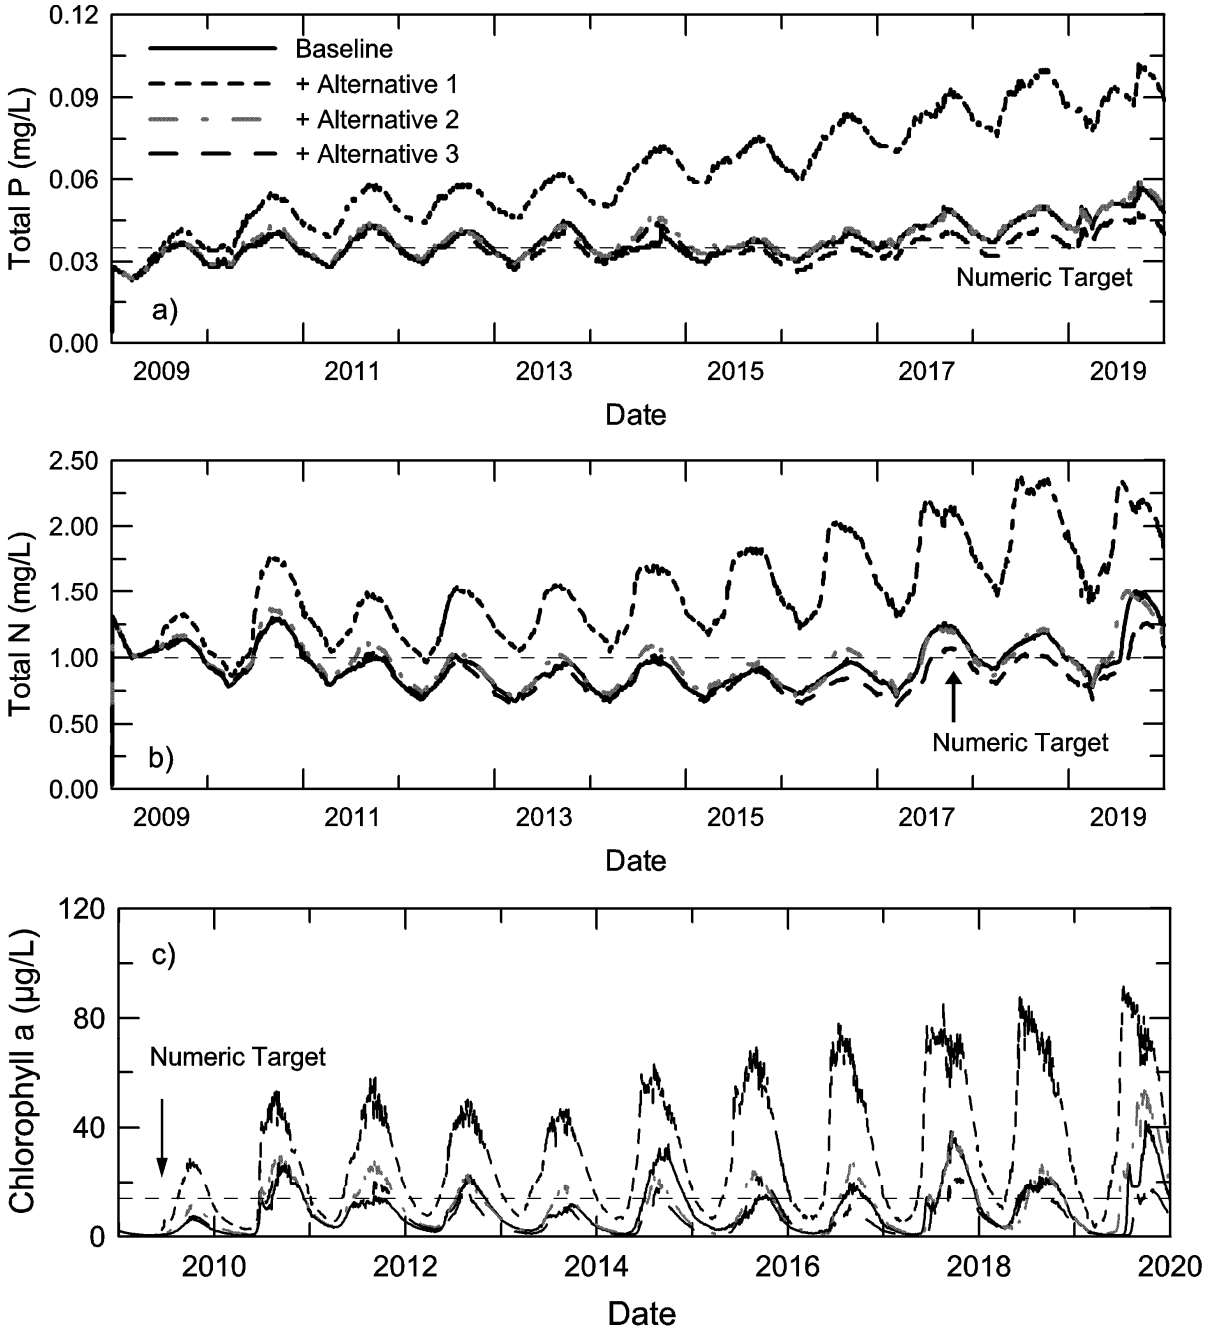

Figure 30. Predicted concentrations of a) total P, b) total N, and c) chlorophyll-a at TMDL station #2 (photic zone).

Supplementation with Alternative 1 effluent also significantly increased littoral plant production, often doubling peak values relative to that predicted under the Baseline scenario and with treatment alternatives 2 and 3 (Figure 31).

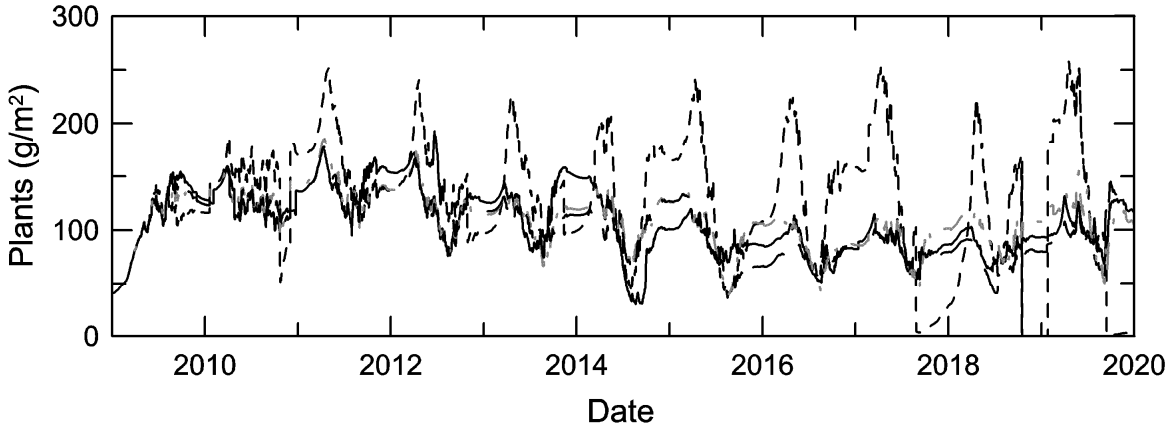

Figure 31. Predicted plant biomass at TMDL station #2 (photic zone). Legend shown in Fig. 30a.

Average concentrations at TMDL station #2 (Gilner Point) for the 11-yr simulation period highlight substantial predicted increases in total P, PO_4-P, and total N resulting from supplementation with Alternative 1 effluent (Table 20). The large increase in P concentrations also yielded a substantial increase in predicted average chlorophyll-a concentration (30.5 vs 9.3 µg/L). Supplementation with Alternative 1 effluent also increased TIN concentrations compared with the Baseline scenario and increased (non-phytoplankton) plant production. Supplementation with Alternative 2 effluent yielded predicted average water quality quite similar to the Baseline scenario, while supplementation with Alternative 3 effluent was predicted to improve average water quality somewhat (Table 22).

Table 22. Average concentrations of nutrients and chlorophyll-a for 2009-2019 period under the Baseline scenario and with supplementation with water from the three Treatment Alternatives.

Scenario	Total N (mg/L)	Total P (mg/L)	Chl a (µg/L)	PO_4-P (µg/L)	TIN (mg/L)	Plants (g/m^2)
Baseline	0.948	0.037	9.3	3.5	0.049	106.9
Alternative 1	1.511	0.063	30.5	7.8	0.120	126.3
Alternative 2	0.979	0.038	10.9	3.6	0.047	110.2
Alternative 3	0.894	0.035	7.1	3.3	0.046	103.1

Supplementation of treated effluent from the BBARWA WWTP is thus predicted to yield different water quality in Big Bear Lake depending upon effluent water quality. Supplementation with Alternative 1 effluent is predicted to substantially increase lake total P and PO_4-P concentrations, which may also increase N_2-fixing blue-green algae, as well as increase epiphyte and macrophyte production. Supplementation with Alternative 2 effluent is predicted to yield water quality conditions similar to natural conditions, while providing increased lake volume, lake surface area, and additional (non-planktonic) plant biomass. Further treatment of effluent in Alternative 3 was predicted to slightly improve water quality compared with that predicted for the 2009-2019 Baseline scenario.

Cumulative distribution functions for basin-wide volume-averaged concentrations of TP and TN highlight the substantial increase in nutrients that would result from the addition of Alternative

1 effluent, while also demonstrating that Alternative 2 effluent is predicted to yield nutrient levels similar to predicted 2009-2019 levels, while supplementation with Alternative 3 effluent is predicted to yield slightly improved (lower) concentrations (Figure 32).

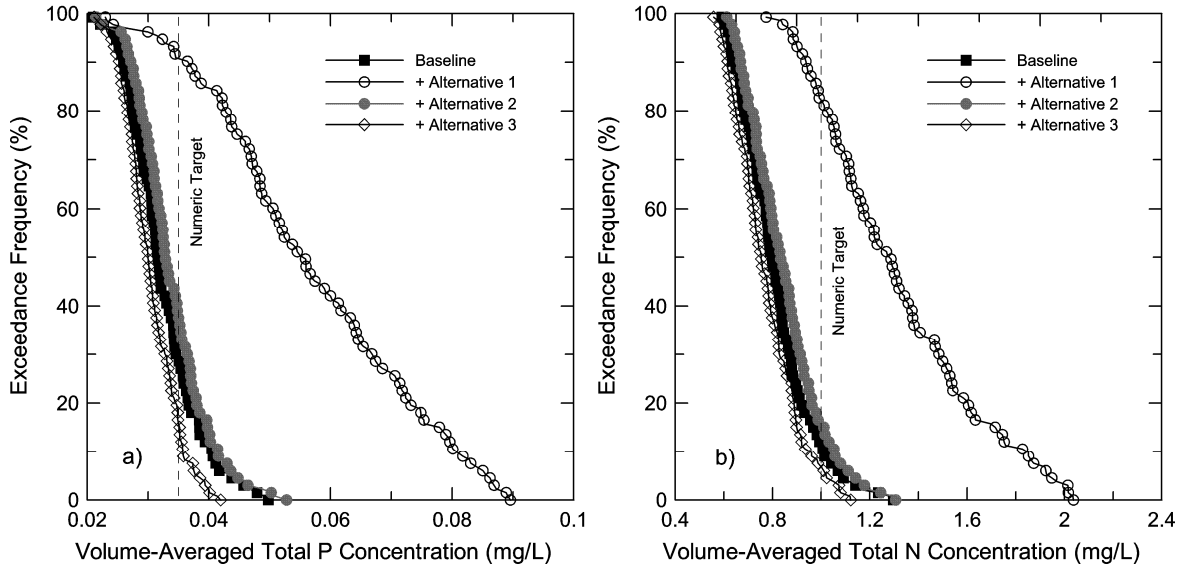

Figure 32. Cumulative distribution functions for predicted baseline and supplementation scenarios of volume-weighted concentrations of a) total P and b) total N.

Summary

Supplementation of natural flows with 1,920 af/yr of Replenish Big Bear water was predicted to add about 0.2 m annually to the lake relative to levels observed in 2009-2019 (baseline), and which accrued over time such that the lake was predicted to be 1.7 m higher in late 2018 compared to the level present at that time. Supplementation also increased lake volume and surface area, with lake area about 300 acres (16%) larger in late 2018 compared with actual area (approximately 2200 acres vs 1900 acres, respectively). Addition of 1,920 af/yr of Alternative 1 water significantly increased TDS levels in the lake, increasing average predicted TDS from 251 mg/L for the baseline (natural) condition for 2009-2019 to 300 mg/L, while Alternatives 2 and 3 were predicted to yield slightly lower average TDS concentrations of 244 and 226 mg/L, respectively. Exceedance of the TDS water quality objective of 175 mg/L was predicted to occur 97.6% of the time for both the baseline condition and for Alternative 2, while exceedance frequency increased to 100% for Alternative 1 and was reduced to 93.3% for Alternative 3.

Nutrient concentrations in the Replenish Big Bear water varied markedly with treatment, with total N and total P concentrations in Alternative 1 being about 6-9x higher than median watershed concentrations, while concentrations in Alternative 2 were projected to be 1.8-2.3x larger and Alternative 3 being about 0.4-0.8x that of median watershed values. The increased nutrient loading from Alternative 1 had a strongly detrimental effect on water quality, increasing average concentrations over 2009-2019 baseline of total N by about 50%, total P by 70%, and chlorophyll-a by 300%. In comparison, further treatment of effluent yielded average

concentrations comparable to (Alternative 2) or slightly improved (Alternative 3) relative to the baseline (natural no-project) condition.

V. PREDICTED LONG-TERM FUTURE CONDITIONS WITH REPLENISH BIG BEAR PROJECT

Simulations were extended from the reference period (2009-2019) to include 30 additional years, for a total of 41 simulation years that yielded potential trajectories for water level, area, TDS, and nutrients out to the beginning of 2050. As previously noted, the model requires extensive data for meteorological conditions (air temperature, dewpoint temperature, wind speed, wind direction, cloud cover, and solar radiation), as well as water inflows, outflows, and withdrawals. While hourly weather forecasts are available 7-10 days in advance from the National Weather Service (NWS) and 5-10 day flow forecasts are available for limited gaged stations from the NWS River Forecast Centers, we obviously do not know *a priori* these detailed meteorological and hydrological conditions for the next 30 years. Similarly, while downscaled global climate models provide some projections about trends in air temperature and precipitation, they do not provide information with sufficient resolution to allow direct use in our simulations.

Given these constraints, existing meteorological and flow data for 2009-2019 were used as the basis for forecasts. (An effort was made to expand the meteorological record to include additional years, but available weather data for the Big Bear Airport only go back to April 2007, thus providing only one additional full year of record, so existing data were used.) The 2009-2019 period included record or near record air temperatures and intervals of both extreme drought and very high precipitation/runoff that captured much of the anticipated inter-annual variability in meteorology and hydrology (e.g., Table 23). For example, average precipitation over 2009-2019 period was not statistically significantly different than that of the past 43 years (e.g., 31.7±15.6 vs 34.8±14.7 in/yr at Bear Valley Dam). Precipitation was better described as log-normally distributed; however, with geometric mean values very similar to median values, and both being slightly lower (reflecting increased prevalence of drought) but well-captured in the 2009-2019 dataset. Perhaps more importantly, minimum and maximum values for the 2009-2019 period were also similar to the larger 1977-2019 dataset (e.g., the highest annual precipitation at the Big Bear Community Services District (BBCCSD) was recorded in 2010, within the 2009-2019 record).

Table 23. Annual precipitation (calendar year) recorded at Bear Valley Dam and BBCCSD. (Water Master, 2019).

Precipitation (in/yr)	Bear Valley Dam		BBCCSD	
	1977-2019	2009-2019	1977-2019	2009-2019
Average	34.8	31.7	14.9	17.5
Geometric Mean	31.6	29.1	13.3	16.3
Median	31.8	27.8	14.1	14.8
Minimum	13.2	14.4	3.8	8.2
Maximum	73.8	64.1	33.2	33.2

Assuming that 2009-2019 is broadly representative of likely future meteorological and hydrologic conditions, Monte Carlo techniques were used to randomly select 100 different 30-year annual records from this set of data. Thus, any given future year was assumed to essentially have a 1-in-11 chance of looking like any one of the years from the 2009-2019 period in terms of meteorological conditions, inflows, withdrawals, and releases for downstream flow

requirements. Impacts of climate change were considered; air temperature increases would increase evaporation losses from lake, but also likely yield more rain and rain-on-snow events that would increase runoff and inflows to lake. Without detailed watershed modeling, it is not possible to resolve these conflicting impacts on the water budget for the lake, so for the purposes of this analysis, they were assumed to cancel out. The Monte Carlo analysis yielded 30-year average flow rates that ranged from 6,891 to 15,115 af/yr (Figure 33). Individual year flow rates varied more widely, ranging from 1,961 – 27,579 af/yr (not shown).

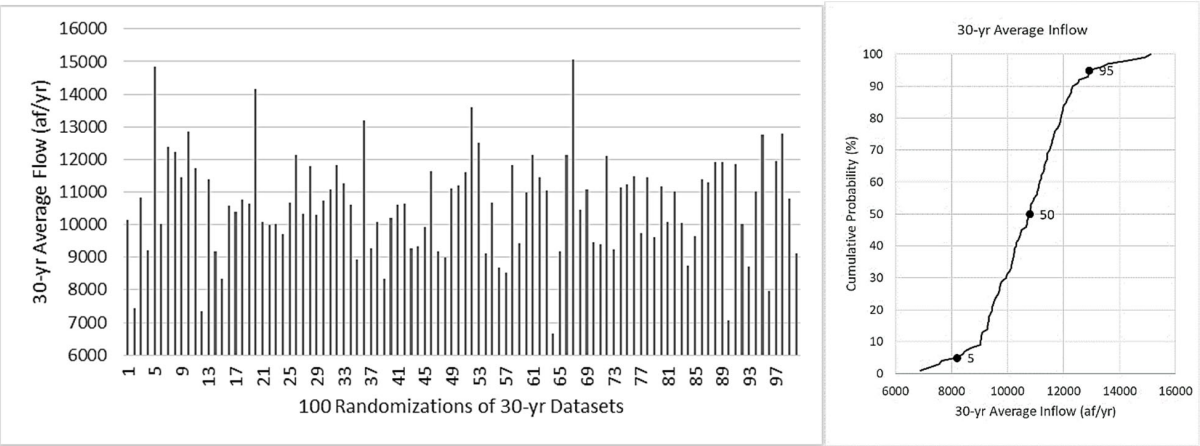

Figure 33. Thirty year average flow rates for 100 random datasets.

From this dataset (Figure 33), three hydrologic scenarios were selected for further analysis corresponding to the 5th-percentile, 50th-percentile (median), and 95th-percentile 30-yr average flow rates. The 5th-percentile corresponds to an average inflow rate of 8,646 af/yr and represents extended drought, not unlike that present in the 1950's-60's, while the 50th-percentile hydrologic scenario corresponds to intervals of both high runoff and drought, comparable to 2009-2019 (average annual inflow of 10,595 af/yr), and the 95th-percentile represents a period of protracted above average rainfall and runoff (average annual inflow of 12,225 af/yr). Cumulative inflows for these 3 hydrologic scenarios are presented in Figure 34. The corresponding meteorological, outflow and withdrawal conditions were used as input for CE-QUAL-W2 simulations. The 3 simulations represent forecasts of conditions subject to the temporal boundary conditions (inflows, meteorological conditions, etc.), and thus are not predictive of conditions at specific points of time in the future. On that basis, results are presented as cumulative distribution functions rather than time-series to convey information in a statistical-probabilistic framework rather than as strict forecasts in time. Lake properties are contrasted between baseline conditions under the 3 hydrologic scenarios and with implementation of the Replenish Big Bear project.

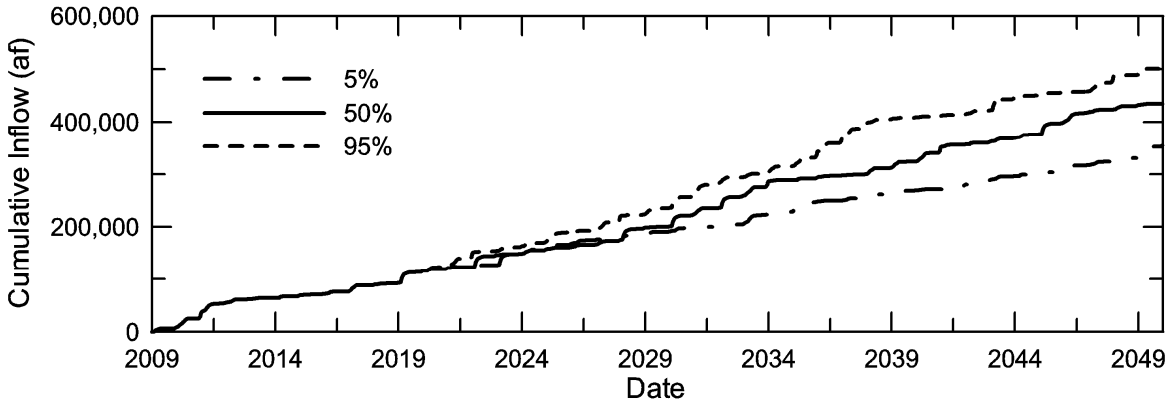

Figure 34. Cumulative inflows under 5th-, 50th- and 95th-percentile 30-yr average hydrologic scenarios.

A. Lake Surface Elevation

The 3 hydrologic scenarios had pronounced effects on predicted lake levels, with the 5th-percentile (chronic drought) scenario yielding elevations as low as 2044.9 m above MSL and a median elevation of 2048.8 m (Figure 35a). The 50th- and 95th-percentile hydrologic scenarios yielded predictably higher lake levels (e.g., median levels of 2052.2 and 2053.1 m, respectively) (Figure 35a). Supplementation with 1,920 af/yr of Replenish Big Bear water markedly increased lake levels, *e.g.*, raising the minimum level for 5th-percentile scenario by up to 4.6 m and increasing median level from 2048.8 m for baseline to 2052.0 m (Figure 35b).

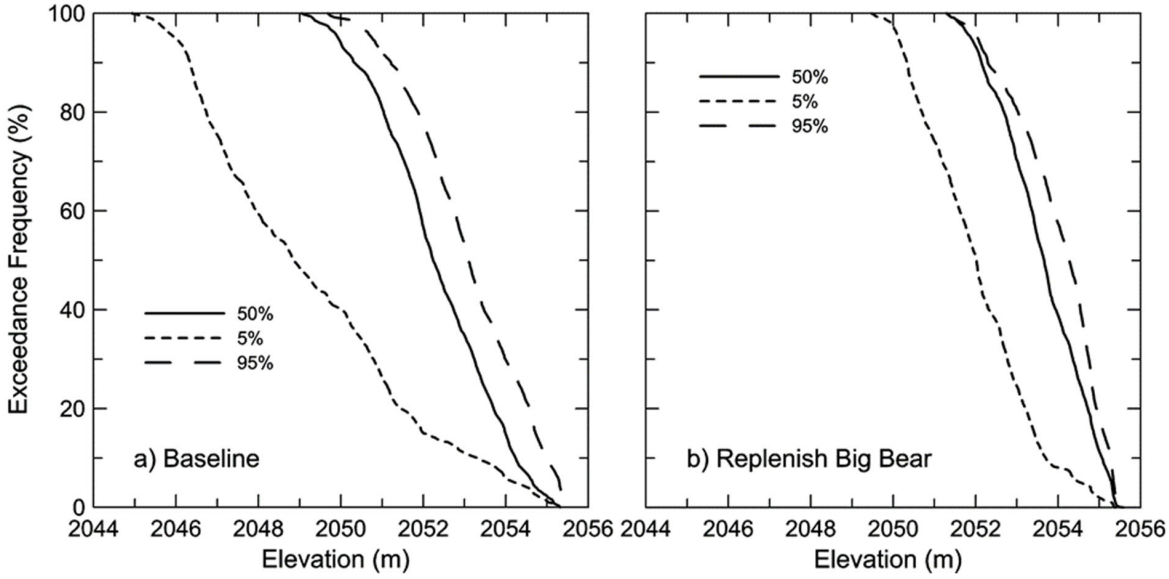

Figure 35. CDFs of predicted lake elevations at 5th-, 50th- and 95th-percentile hydrologic scenarios for a) baseline conditions and b) supplementation with Replenish Big Bear water.

B. Lake Volume

Supplementation also substantially increased lake volumes, with volumes potentially as low as 6,000 af and a median volume of about 23,000 af for the 5th-percentile (drought) scenario (Figure 36). Supplementation with Replenish Big Bear water resulted in significant increases in lake volume for the other hydrologic scenarios as well (Figure 36).

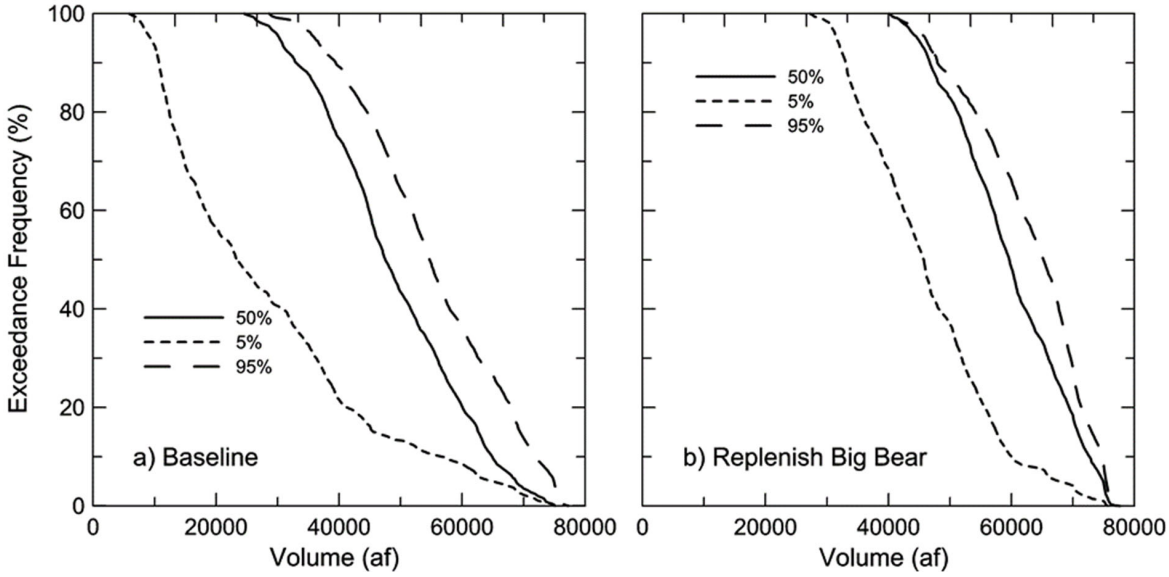

Figure 36. CDFs of predicted lake volumes at 5th-, 50th- and 95th-percentile hydrologic scenarios for a) baseline conditions and b) supplementation with Replenish Big Bear water.

C. Lake Surface Area

The 5th-percentile hydrologic scenario also yielded very low lake surface areas, potentially <1000 acres and a median area of about 1700 acres (Figure 37a). The minimum predicted lake surface areas were about 2x larger and median surface areas were approximately 2300 and 2500 af for the 50th- and 95th-percentile hydrologic scenarios, respectively. Supplementation substantially increased lake area, shifting all CDFs to higher area values (Figure 37b). This can be seen more graphically in Figure 38, where the areas corresponding to the minimum and 75% exceedance frequencies (predicted to occur 25% of the time under the simulated protracted drought condition) are projected onto the natural lake boundary for the baseline and with project. At the minimum area, the lake divides into the impounded area behind the dam and a 2nd very shallow mid-basin, while the Project is able to maintain an extensive and contiguous lake area through the main body of the lake (Figure 38a). A considerable additional area is also maintained at the 75% exceedance frequency with supplementation (Figure 38b).

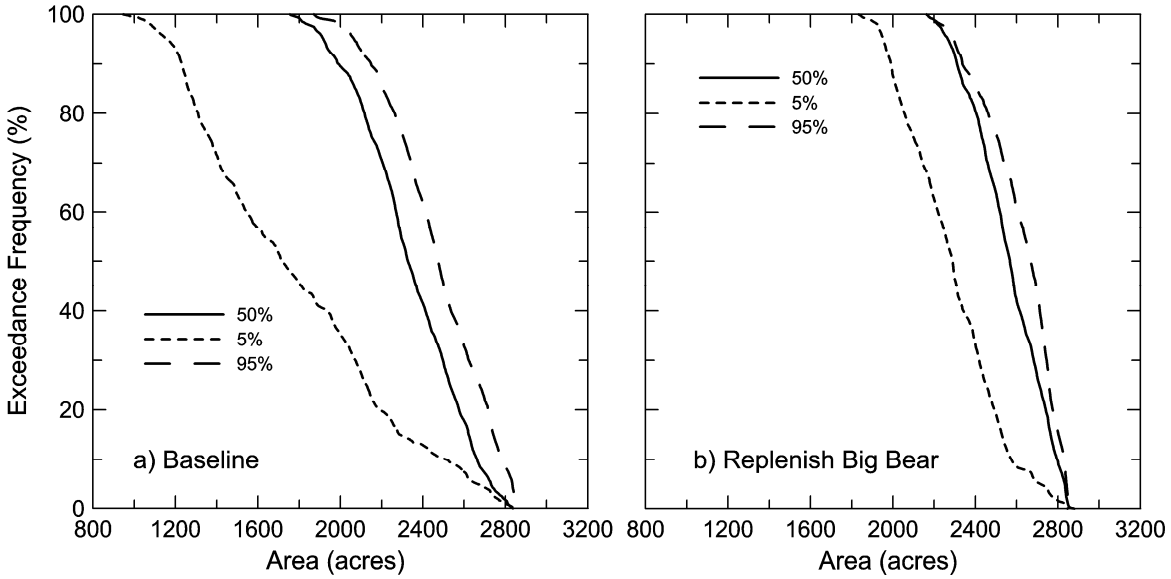

Figure 37. CDFs of predicted lake areas at 5th-,50th- and 95th-percentile hydrologic scenarios for a) baseline conditions and b) supplementation with Replenish Big Bear water.

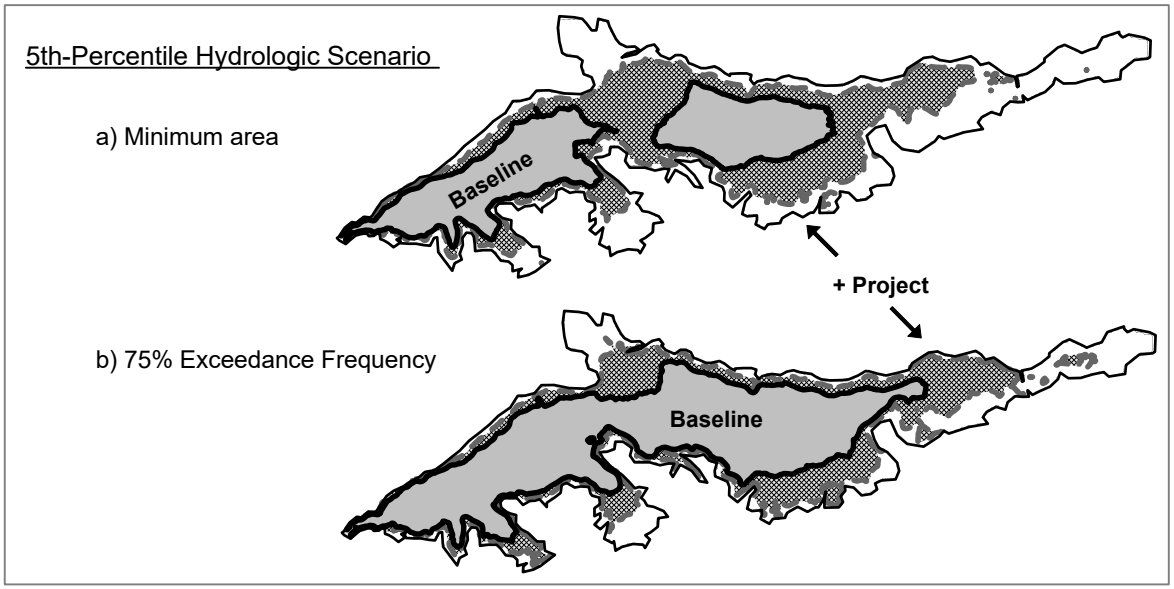

Figure 38. Lake surface under 5th-percentile flows (protracted drought) depicting areas under baseline conditions (solid gray) and with project (cross-hatched) at a) minimum area and b) 75% exceedance frequency (predicted to occur 25% of the time under the simulated protracted drought condition).

D. Total Dissolved Solids

The concentrations of TDS in Big Bear Lake vary naturally as a function of lake level as a result of runoff inputs and evapoconcentration. Thus, predicted TDS concentrations were greatest for the 5th-percentile hydrologic scenario (protracted drought) and lower for the 50th- and 95th-percentile hydrologic scenarios (Figure 39a). Unlike lake elevation, volume and area which are independent of the type of effluent treatment, predicted TDS concentrations in the lake are quite sensitive to it (Figure 39b-d).

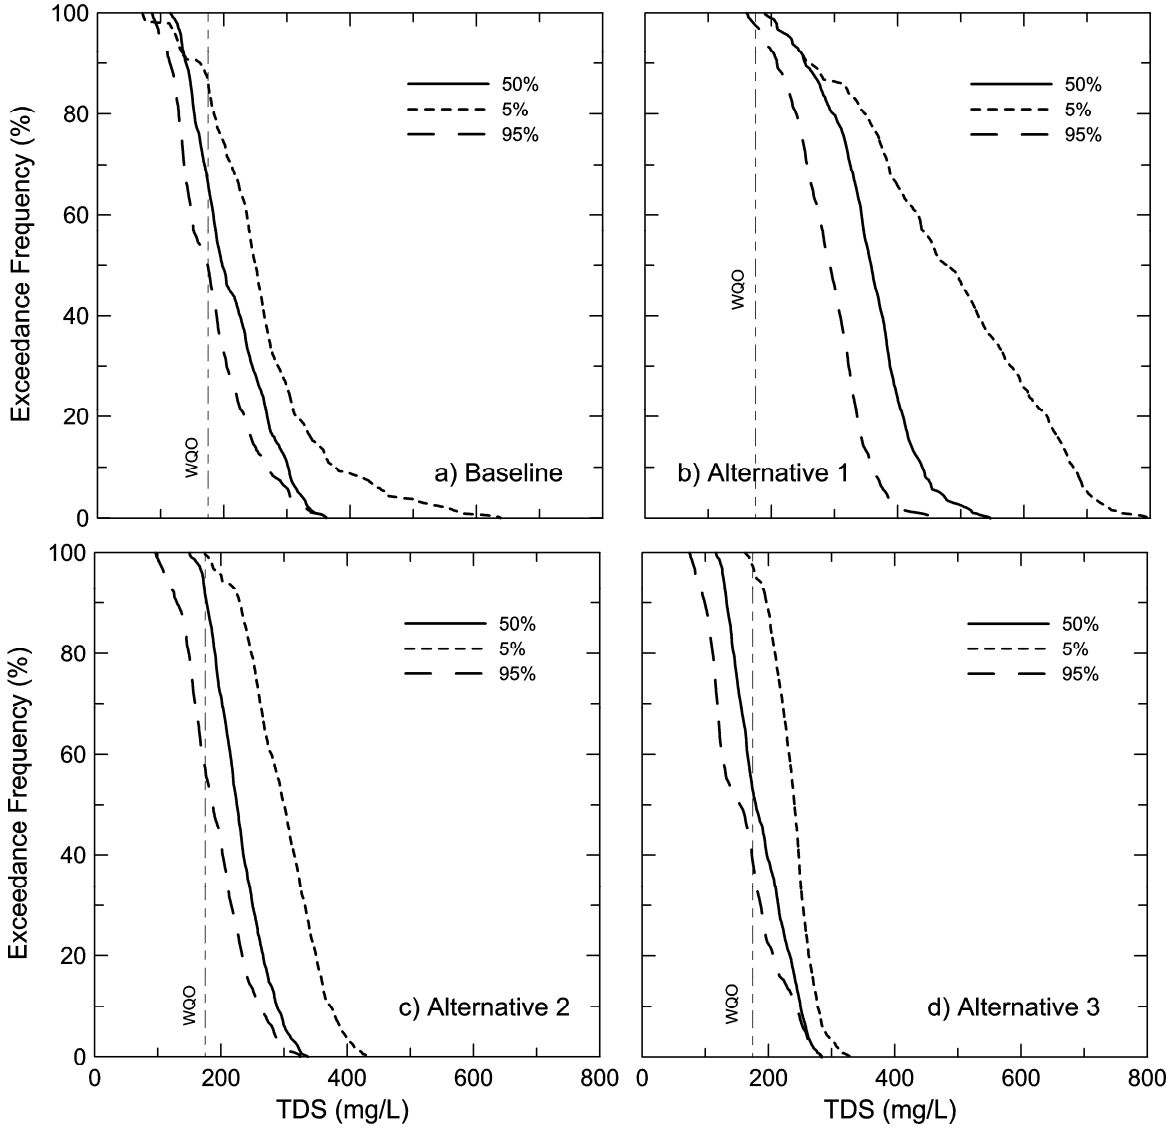

Figure 39. CDFs of predicted lake TDS at 5th-,50th- and 95th-percentile flows for a) baseline conditions, and supplementation with b) Alternative 1, c) Alternative 2 and d) Alternative 3 water.

Alternative 1 treatment, involving only nutrient removal, yielded high concentrations of TDS that was predicted to exceed the water quality objective by wide margins (Figure 38b), while Alternative 2 shifted CDFs from baseline to slightly higher TDS levels, and the highest level of treatment (Alternative 3) yielded slightly lowered concentrations relative to Baseline scenario (Figure 39c,d).

E. Total P

Total P concentrations for the baseline condition were predicted to vary under the 3 hydrologic scenarios, exceeding 0.05 mg/L with some frequency under the drought scenario (Figure 40a).

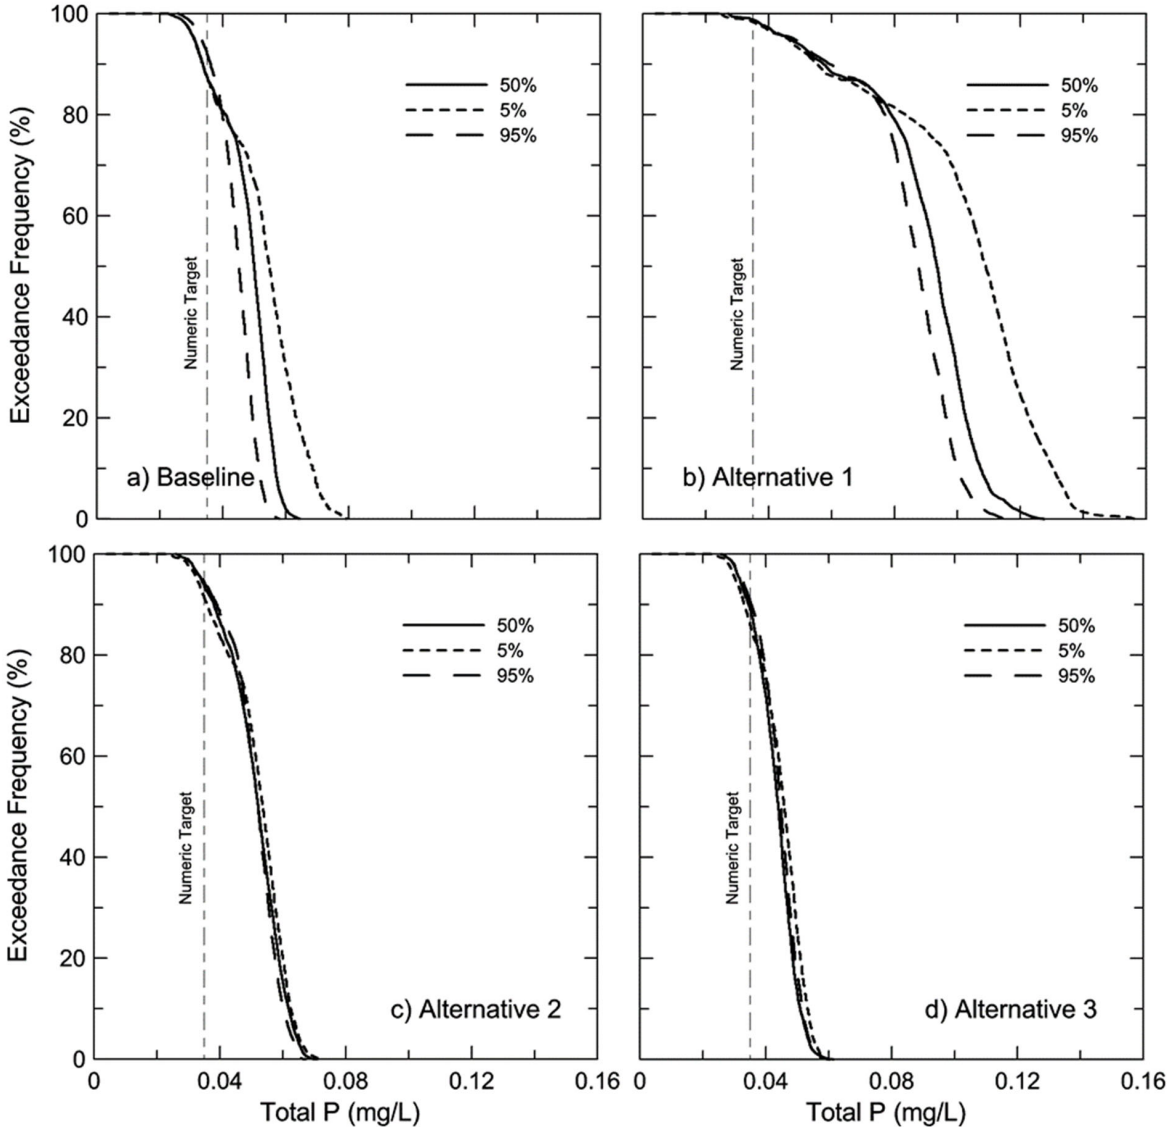

Figure 40. CDFs of predicted total P levels at 5th-, 50th- and 95th-percentile hydrologic scenarios for a) Baseline, and supplementation with b) Alternative 1, c) Alternative 2 and d) Alternative 3 water.

As noted in simulations for 2009-2019, supplementation with Replenish Big Bear effluent substantially degraded predicted water quality, and increased total P (Figure 40b), as well as total N (Figure 41b) and chlorophyll-a (Fig. 42b). Supplementation with higher quality Alternative 2 and 3 water reduced natural variability and provided comparable or lower levels (Figure 40c,d).

F. Total N

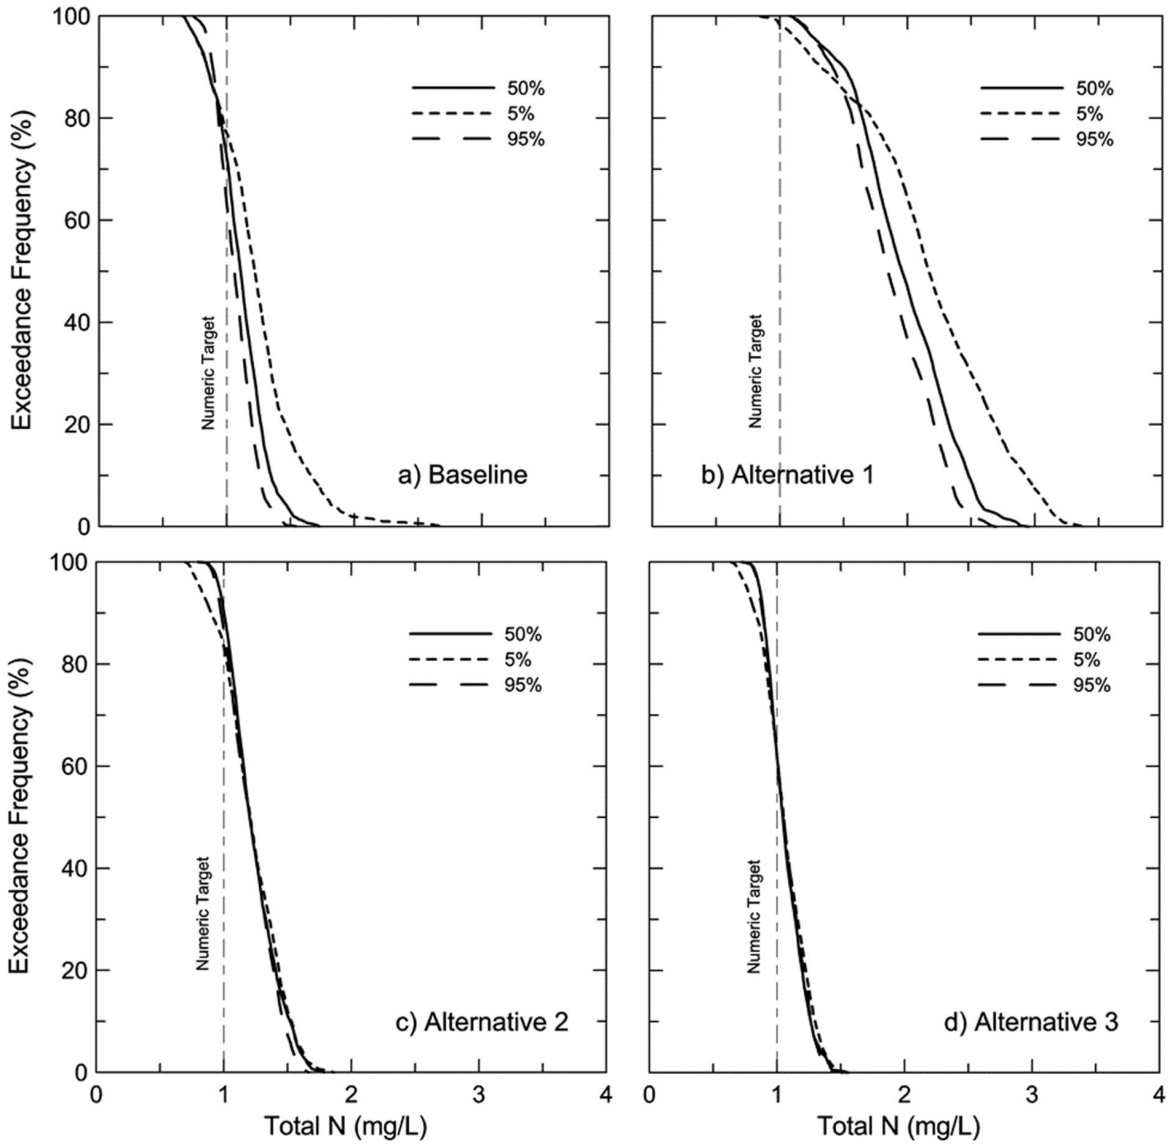

Figure 41. CDFs of predicted total N levels at 5th-, 50th- and 95th-percentile hydrologic scenarios for a) baseline conditions, and supplementation with b) Alternative 1, c) Alternative 2 and d) Alternative 3 water.

Predicted total N concentrations (Figure 41) followed the same trends as total P (Figure 40), with Alternative 1 significantly increasing concentrations, while Alternatives 2 and 3 reduced variability in baseline case due to stabilization of lake level with high quality water (Figure 41).

G. Chlorophyll-a

Chlorophyll-a concentrations followed similar trends as noted for total P and total N, with a >5x increase in median predicted concentrations with Alternative 1 compared with baseline, while Alternatives 2 and 3 yielded comparable or slightly higher predicted concentrations (Figure 42).

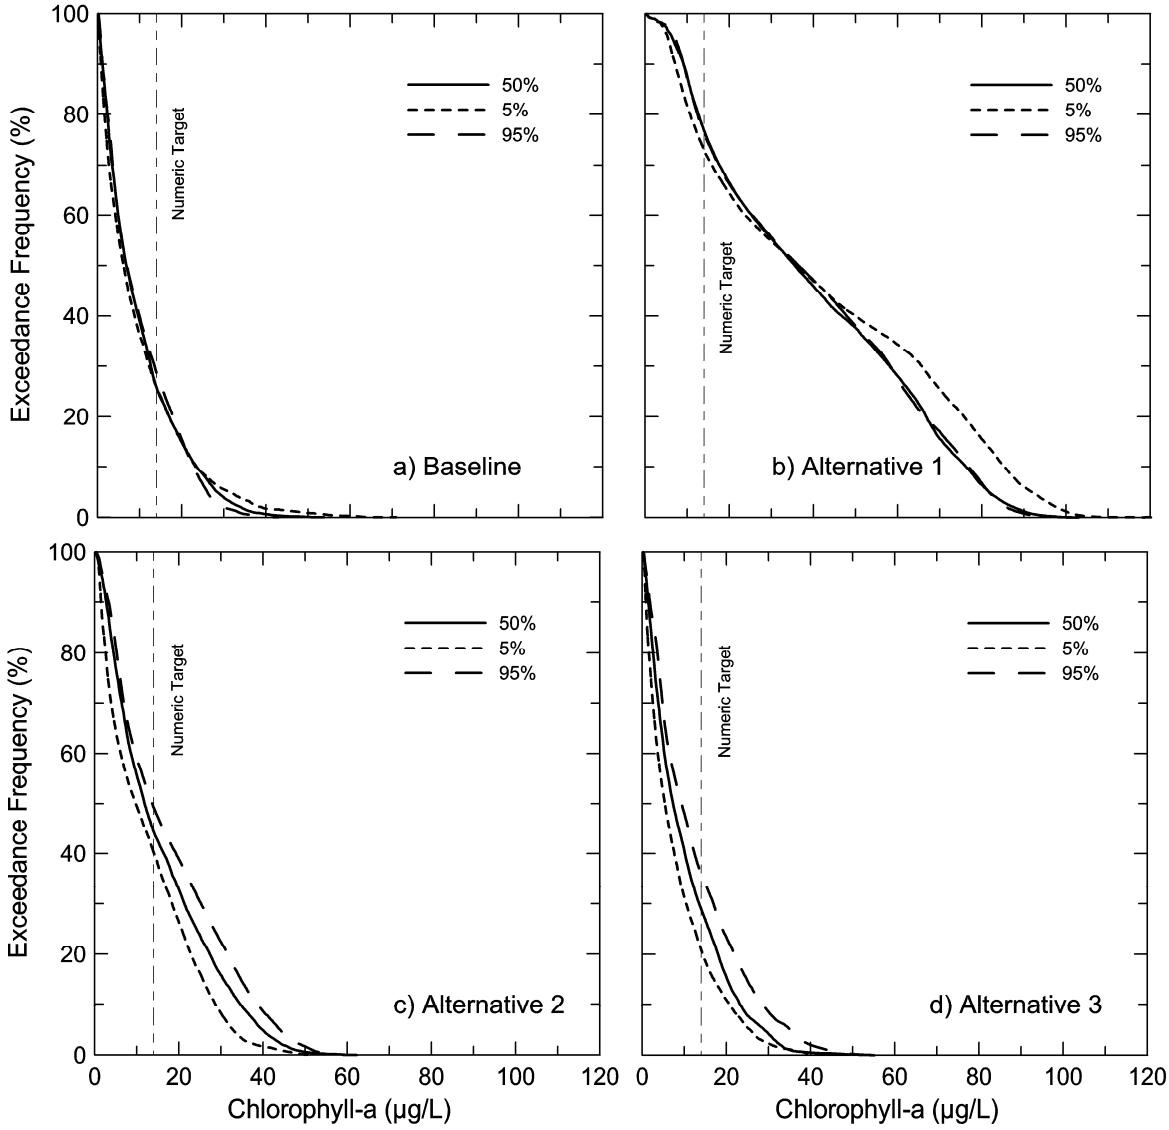

Figure 42. CDFs of predicted chlorophyll-a levels at 5th-, 50th- and 95th-percentile hydrologic scenarios for a) Baseline, and supplementation with b) Alternative 1, c) Alternative 2 and d) Alternative 3 water.

CDF Summary

CDFs convey a great deal of information, although it is often not easy to readily resolve differences across multiple graphs. Median lake dimensions for the 3 different hydrologic scenarios with and without supplementation with water from the Replenish Big Bear project from Figures 34-36 are summarized in Table 24.

Table 24. Influence of hydrologic scenarios and supplementation on median lake dimensions.

Parameter	Scenario	5th-Percentile	50th-Percentile	95th-Percentile
Elevation (m)	Baseline	2048.9	2052.2	2053.1
	+Project	2052.0 (+3.2)	2053.7 (+2.2)	2054.3 (+1.6)
Volume (af)	Baseline	23,404	47,536	54,724
	+Project	45,746 (+22,342)	59,664 (+12,128)	65,204 (+10,480)
Area (acres)	Baseline	1717	2328	2474
	+Project	2290 (+572)	2568 (+240)	2669 (+195)

Median concentrations of TDS, total N, total P and chlorophyll-a under the different hydrologic scenarios and levels of treatment are summarized in Table 25. As evident in the CDFs, the level of treatment of the supplemental water substantially affects the resulting water quality in the lake. Treated effluent with nutrient removal (Alternative 1), without additional treatment, offsets or other strategies, is predicted to have significant negative impacts to water quality in the lake, nearly doubling median concentrations of total P and total N, and increasing median chlorophyll-a concentrations by >5x relative to levels predicted for the natural (baseline) scenario (Table 25). Further advanced treatment of effluent (Alternatives 2 and 3), however, yielded predicted water quality broadly similar to or slightly better than the baseline case (Table 25).

Table 25. Influence of hydrologic scenarios and supplementation with alternative levels of treatment on predicted median concentrations of TDS, total N, total P and chlorophyll-a.

Parameter	Scenario	5th-Percentile	50th-Percentile	95th-Percentile
TDS (mg/L)	Baseline	250	198	175
	Alternative 1	478	358	293
	Alternative 2	300	225	187
	Alternative 3	241	180	155
Total P (mg/L)	Baseline	0.055	0.050	0.045
	Alternative 1	0.109	0.094	0.088
	Alternative 2	0.054	0.052	0.052
	Alternative 3	0.046	0.044	0.045
Total N (mg/L)	Baseline	1.22	1.11	1.06
	Alternative 1	2.17	1.96	1.85
	Alternative 2	1.21	1.20	1.20
	Alternative 3	1.05	1.05	1.05
Chlorophyll-a (µg/L)	Baseline	6.2	6.9	7.0
	Alternative 1	36.1	35.6	36.5
	Alternative 2	9.7	11.9	13.7
	Alternative 3	5.4	7.3	9.4

Summary

Simulations for 2009-2019 were extended to 2050 to evaluate possible long-term conditions in the lake under natural hydrologic variability with and without supplemental water from

Replenish Big Bear. Three hydrologic scenarios representing the 5th-, 50th- and 95th-percentile 30 year average annual flow records were used for predictions of future conditions in the lake. The 5th-percentile corresponded to an average inflow rate of 8,646 af/yr and represents extended drought, while the 50th-percentile (median) corresponded to intervals of both high runoff and drought comparable to 2009-2019 (average annual inflow of 10,595 af/yr), and the 95th-percentile represented a period of protracted above average rainfall and runoff (average annual inflow of 12,225 af/yr).

Supplementation with Replenish Big Bear was predicted to influence long-term (2009-2050) conditions in the lake which varied under the 3 hydrologic scenarios. Under the 50th-percentile hydrologic scenario, Replenish Big Bear was predicted to increase average lake level by 1.5 m, lake volume by nearly 13,000 af, and lake area by 260 acres relative to the predicted long-term baseline (no-project) condition. Water quality varied with level of effluent treatment, with Alternative 1 nearly doubling predicted long-term average concentrations of TDS, total P and total N and quadrupling average predicted chlorophyll-a levels. Long-term simulations indicate slight increases in average TDS, total P and total N and modest increase in chlorophyll-a for Alternative 2, and generally slight reductions or no significant change in concentrations with Alternative 3. Supplementation was predicted to have more substantial effects under the 5th-percentile hydrologic (drought) scenario, providing an average increase in lake level of 3.4 m, increase in volume of 16,104 af, and an additional average 638 surface acres (about 40% increase) relative to baseline. As with the 50th-percentile hydrologic scenario, supplementation with Alternative 1 effluent substantially degraded lake water quality, while further treatment as provided in Alternatives 2 and 3 yielded comparable or slightly improved water quality in the lake. Effects of Replenish Big Bear were more modest at the 95th-percentile runoff scenario, when supplementation is less important, owing to the lower overall contributions of water and TDS and nutrients relative to the watershed.

VI. ROUTING OF SUPPLEMENTAL WATER THROUGH STANFIELD MARSH

Simulations involved the delivery of Replenish Big Bear project water through Stanfield Marsh and into the main body of the lake. Wetlands are often very good at improving water quality by filtering and settling out of particulate matter, biological uptake of dissolved forms of nutrients, and under favorable conditions also denitrification and loss of NO_3-N to the atmosphere. Stanfield Marsh was predicted to be an effective sink for total P in supplemental water with Treatment Alternatives 1 and 2 but was a modest source of total P for Alternative 3 water (Figure 43, Table 26).

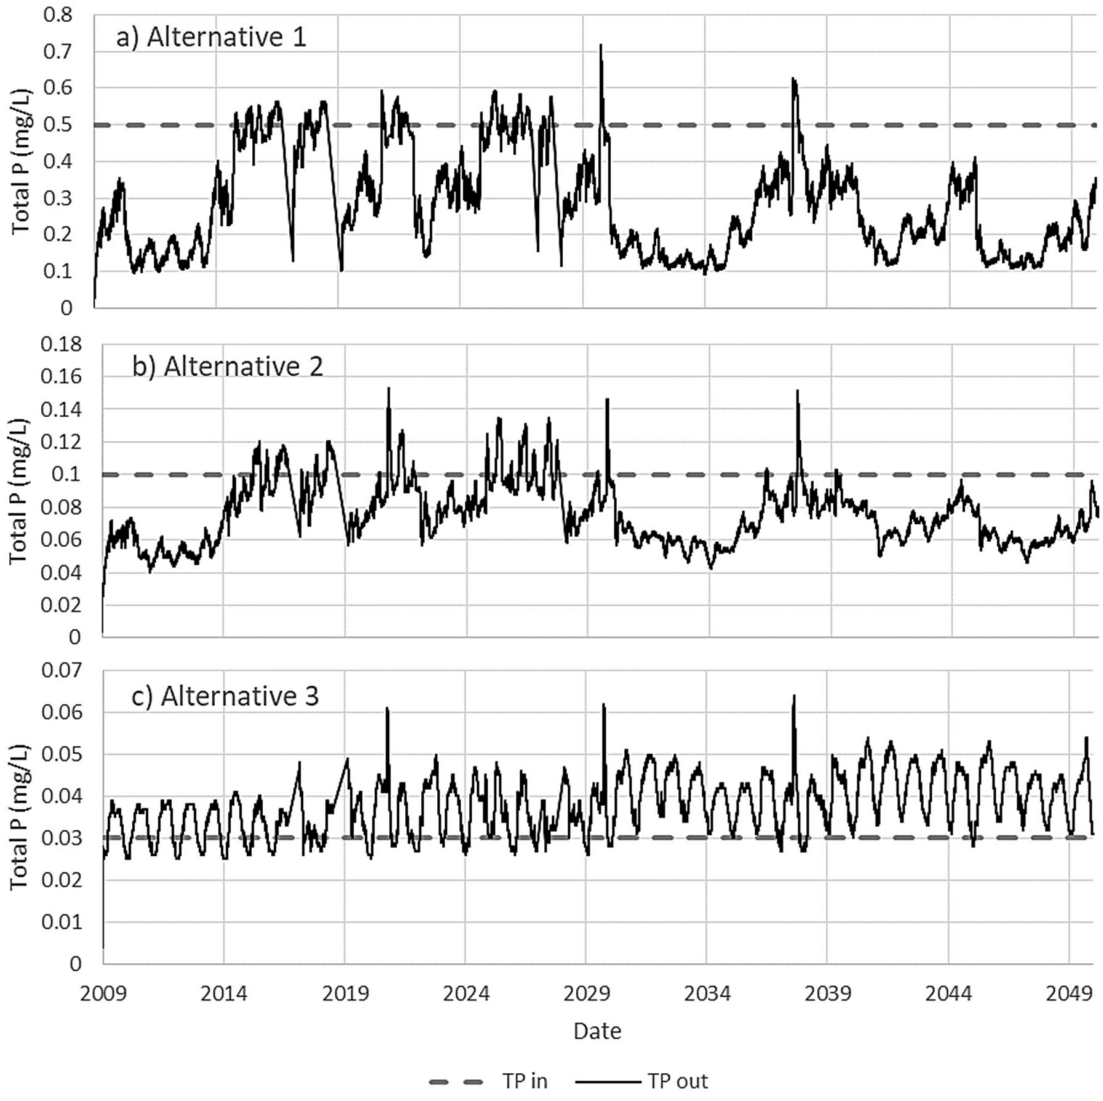

Figure 43. Total P concentrations into and out of Stanfield Marsh: a) Alternative 1, b) Alternative 2, and c) Alternative 3.

Interestingly, the marsh was predicted to be a net source of N for all 3 treatment scenarios; the basis for this is not entirely clear at this time, but sediment mineralization and potentially some N_2-fixation may be occurring during periods of intense primary production that could increase the total N concentration. Stabilization of the water level within the marsh through some hydraulic control would presumably increase nutrient retention and could promote denitrification, although additional work is needed to understand the dynamics within the Marsh, especially given natural variations in lake levels and intervals of wetting and desiccation.

Table 26. Predicted average total P and total N removal in Stanfield Marsh.

	Alternative 1		Alternative 2		Alternative 3	
	% Removal	kg/yr	% Removal	kg/yr	% Removal	kg/yr
Total P	14.8	175	8.4	20	-10.3	-7
Total N	-22.5	-1174	-17.0	-442	-19.0	-270

Summary

Simulations indicate net removal of total P from Alternative 1 and Alternative 2 effluents during flow through Stanfield Marsh, while the Marsh was predicted to be a modest source of total P to Alternative 3 water with very low influent concentrations. Interestingly, the Marsh was predicted to be a source of total N across all levels of treatment, due presumably to sediment decay, some N_2-fixation and subsequent decay in response high PO_4-P concentrations and high TN:TP ratios in the effluent. Further work is needed, however, to better understand the role of the Marsh as a net sink and/or source for nutrients.

VII. SUMMARY

Lake conditions and water quality in Big Bear Lake varied significantly over 2009-2019, with wide natural variations in lake level, volume and surface area, as well as concentrations of TDS, nutrients and chlorophyll-a. Statistical, machine learning and hypolimnetic mass balance analyses provided valuable new information about water quality in Big Bear Lake, while CE-QUAL-W2 was able to reproduce observed trends in lake conditions. Supplementation of natural runoff with Replenish Big Bear water significantly increased lake levels, volumes and surface areas, especially during periods of drought, with resulting recreational, aesthetic, community and related benefits. The level of treatment had dramatic effects on water quality, however. Nutrient removal (Alternative 1) was not sufficient to protect water quality in Big Bear Lake, although nutrient removal with further treatment (Alternatives 2 and 3) was predicted to yield water quality comparable to or slightly improved relative to baseline conditions.

Introduction

It was previously noted that water quality was predicted to vary markedly with the level of treatment of added Replenish Big Bear (RBB) recycled water, with Alternative 1 (TIN and TP removal) significantly degrading water quality in Big Bear Lake relative to predicted baseline conditions, while Alternative 2 (70% RO) modestly increased average predicted concentrations of TN, TP and chlorophyll-a, and Alternative 3 (100% RO) was predicted to slightly improve average water quality for the 2009-2019 period (Anderson, 2021, Table 22). Long-term simulations for different hydrologic scenarios yielded similar results, with 100% RO yielding predicted water quality typically comparable to baseline conditions. Notwithstanding, some subtle differences were observed between predicted median baseline concentrations and those for Alternative 3 which assumed steady annual flows of 1920 af/yr of 100% RO water (Anderson, 2021, Table 25).

Recent engineering work indicates that slightly higher inflows, up to 2210 af/yr, can be attained by the Replenish Big Bear project by employing additional brine minimization technology (Table 1). Note that a portion of the water produced by RBB may be discharged to Shay Pond and the earlier "Alternative 3" scenario had excluded those flows (up to 80 af/yr) from the analysis. However, to be conservative for permitting purposes, this analysis is based on discharging all of the recycled water produced to the Lake.

Table 1. Initial and recently updated Replenish Big Bear (RBB) flow projections.

Scenario	**Annual RBB Inflow (af)**	**Daily RBB Inflow (MGD)**
Baseline	0	0
Alternative 3 [(a)]	1920	1.71
High Flow (99% recovery) [(b)]	2210	1.57 – 2.18
Mid Flow (90% recovery) [(b)]	2009	1.42 – 1.98

Notes:

[(a)]Alternative 3 was assessed in the 2021 Lake Analysis and assumed that of the total Replenish Big Bear effluent contribution considered in the Lake Analysis (i.e., 2,000 AFY), 80 AFY would be delivered to Shay Pond. Therefore, only 1,920 AFY would be discharged to the Lake.

[(b)]The updated model analysis assumed that no discharge to Shay Pond would occur and all recycled water would be discharged to the Lake under two different total recovery rates scenarios.

Moreover, deliveries are expected to vary seasonally (Fig 1), thus varying from the earlier "Alternative 3" scenario that assumed uniform flows of 1.71 MGD throughout the year. Inflows to the WWTP are lower in the summer months due to reduced inflow.

Since the Replenish Big Bear project does not have a waste load allocation for total P (TP) in the current TMDL, it is proposing to offset the TP load in the project inflows delivered to Big Bear Lake. While RO is extremely effective at removing dissolved and particulate substances, there nonetheless is a small quantity of TP that is expected to evade treatment (the projected RO effluent concentration is 0.03 mg/L, principally as o-PO_4-P). Elimination of all TP through the treatment process is not practicable, so removal of an equivalent load of TP (up to 200 lbs/yr) from elsewhere in the lake or watershed will be necessary.

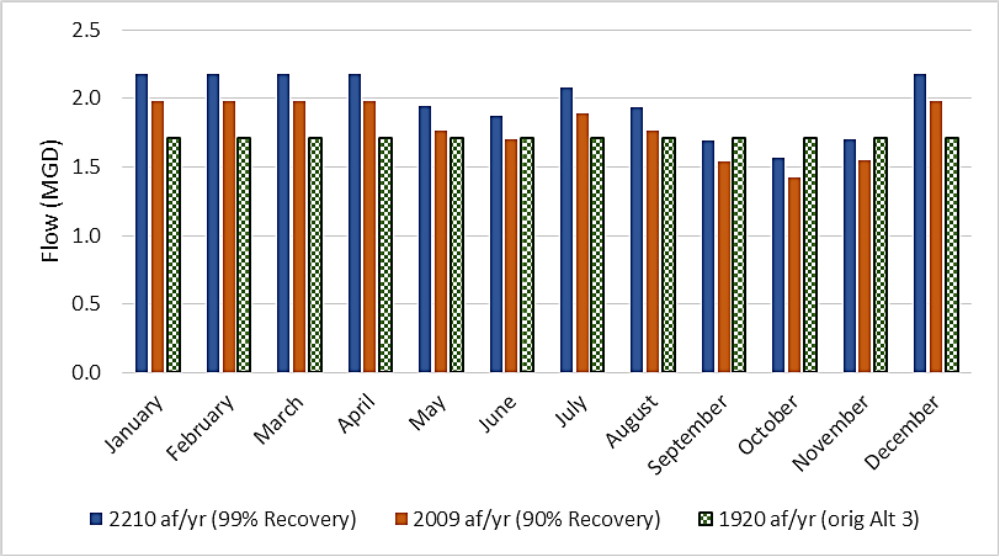

Fig. 1. Monthly flow rates (projected 2040) for Replenish Big Bear under three project inflow scenarios.

In light of these factors, further modeling was conducted to evaluate predicted water quality under these operational scenarios (increased and time-varying flows, with and without TP offset) for comparison with the previously predicted baseline condition and Alternative 3 scenario. Given the complexity of nutrient budgets of lakes, array of possible offset strategies, and equivalence of a given form of nutrient irrespective of its particular origin, TP offset will be modeled as equivalent to 0 influent concentration. This is an approximation that holds when considering whole-lake nutrient budget, but is nonetheless a simplification; depending upon details of offset, hydrodynamic considerations and other factors, some modest lateral gradients in water quality may result. The 50th percentile hydrologic scenario for 2009-2050 was used in this analysis, noting that it includes a wide array of runoff conditions, included extended drought and as well as periods of high runoff. All other hydrologic, meteorological, biological, chemical and sedimentological factors, variables and conditions were identical to those used in prior simulations of long-term future conditions (Anderson, 2021).

Results

Long-term averaged predicted concentrations of TDS, TIN, total P, total N and chlorophyll-a were lower with addition of RBB water compared with predicted baseline conditions (no supplementation) (Table 2). For reference, TMDL target values are included in the table. Focusing on chlorophyll-a as the key response target, baseline conditions were predicted to yield growing-season average chlorophyll-a concentration that slightly exceeded (by 0.1 µg/L) the TMDL target value of 14 µg/L, while Alternative 3 matched the target value, and larger inputs of RBB inflow that varied seasonally (Fig. 1) yielded values below baseline and TMDL target values (Table 2). Zeroing out the load of TP in RBB inflow yielded further reductions in chlorophyll-a; larger inflow volumes with reduced summer flows and no net TP loading were predicted to yield growing season average chlorophyll-a concentrations as low as 9.5 - 10.2 µg/L, significantly below predicted baseline and TMDL concentrations (Table 2).

Table 2. Long-term average predicted concentrations of total P, total N and chlorophyll-a in Big Bear Lake under different operational scenarios (total P and total N expressed as annual average concentrations; chlorophyll-a shown as growing season average concentrations).

Operational Scenario (all at 50th % hydrology)	**TDS (mg/L)**	**TIN (mg/L**	**Total P (µg/L)**	**Total N (mg/L)**	**Chlorophyll-a (µg/L)**
Baseline	**195**	**0.069**	**47.7**	**1.15**	**14.1**
Alternative 3 (1920 af)	182	0.052	43.3	1.07	14.0
2210 af (99% recovery)	**179**	**0.045**	**42.3**	**1.04**	**13.1**
2009 af (90% recovery)	**180**	**0.041**	**43.4**	**1.06**	**12.9**
2210 af + 0 total P	179	0.072	39.9	1.00	10.2
2009 af + 0 total P	180	0.040	40.9	1.00	9.5
TMDL target			***35.0***		***14.0***

Supplementation with RBB inflow also lowered concentrations of total P and total N relative to predicted baseline levels (Table 2). This is consistent with the reduced concentrations of total N and total P (and most dissolved forms of N and P) in RO water relative to watershed runoff concentrations (Anderson, 2021, Table 20), with concentrations projected to be only 40% - 80% of average watershed runoff concentrations (Anderson, 2021, Table 21). Interestingly, zeroing out the influent TP concentration not only lowered the predicted average total P concentration but also reduced the predicted total N concentrations, highlighting the complex biogeochemical coupling of these two key nutrients. While it is important to recognize the uncertainty in model predictions, it is nonetheless noteworthy that revised project flows, with varying seasonal flow and TP offset, yielded average chlorophyll-a concentrations significantly below baseline and TMDL values and also yielded long-term average TN concentrations approaching or reaching 1 mg/L, which is being considered by the Regional Water Board. Predicted long-term average TP concentrations remained above the TMDL target, but were nonetheless meaningfully lower than the predicted baseline level (Table 2). Average TDS and TIN concentrations were also lower than predicted baseline conditions (with exception of 2210 af + 0 TP, where a period of higher NO_3-N was predicted).

Inter-annual differences in water quality are nonetheless expected to persist. Cumulative distributions functions (CDFs) highlight the predicted wide range in annual and growing season average concentrations (Fig. 2). While addition of RBB inflow shifted CDFs to lower annual average total P and total N concentrations and growing season average chlorophyll-a concentrations, wide ranges in predicted concentrations remained in place (Fig. 2). Thus, the growing season average chlorophyll-a target of 14 µg/L was predicted to be exceeded about 53% of the time under baseline conditions, and exceeded about 41% and 31% of the time with RBB inflows of 2210 af/yr without and with TP offset, respectively (Fig. 2c; Table 3). Results for all scenarios are summarized in Table 3.

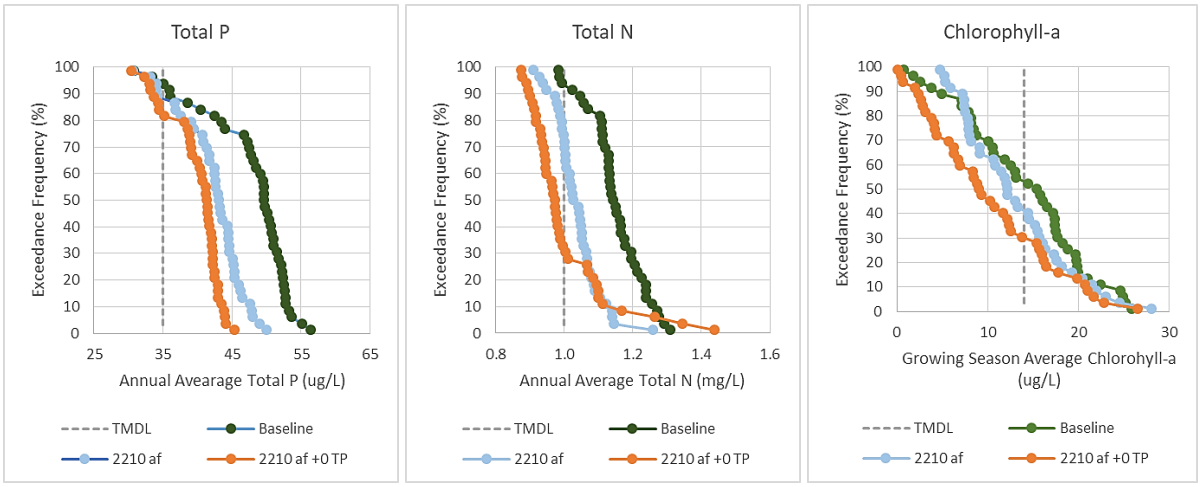

Fig. 2. Cumulative distribution functions for predicted annual total P and total N concentrations and growing season average chlorophyll-a concentrations for baseline condition and with 2210 af RBB inflow with and without TP offset.

Table 3. Predicted frequency of exceeding TMDL target under baseline conditions and different RBB inflow and TP offset scenarios (annual average or growing season average basis). Observed annual exceedance frequencies for 2009-19 period shown in parentheses under Baseline.

Variable	**Baseline**	**1920 af**	**2210 af**	**2210 af+0 TP**	**2009 af**	**2009 af+0 TP**
Total P	94 % (100%)	87 %	87 %	82 %	91 %	90 %
Total N[a]	91 % (na)	72 %	72 %	30 %	80 %	55 %
Chlorophyll-a	53 % (55%)	51 %	41 %	31 %	40 %	22 %

EXECUTIVE SUMMARY

Project Description

The Big Bear Area Regional Wastewater Agency (BBARWA) operates an existing regional wastewater treatment plant (WWTP) and related facilities in the Big Bear Valley (Valley). BBARWA has partnered with Big Bear City Community Service District (BBCCSD), Big Bear Lake Department of Water and Power (BBLDWP), Big Bear Municipal Water District (BBMWD), and Bear Valley Basin Groundwater Sustainability Agency (BVBGSA), collectively known as the Agency Team, to develop the Replenish Big Bear Program. The Replenish Big Bear Program is intended to help protect the Valley and the Santa Ana Watershed from the impacts of drought and variable precipitation by recovering a water resource currently discharged outside of the watershed. The program is comprised of several elements; the first project includes treatment upgrades at the BBARWA WWTP to produce disinfected, advanced treated effluent by providing tertiary filtration, reverse osmosis (RO) treatment, and ultraviolet (UV) disinfection for 100% of the water proposed to be discharged to Stanfield Marsh Wildlife and Waterfowl Preserve (Stanfield Marsh), a tributary of Big Bear Lake (Lake) and a separate discharge to Shay Pond, a tributary of Shay Creek. These discharges are referred to as the "Lake discharge" and the "Shay Pond discharge" and the approximate discharge locations are shown in **Figure ES-1**.

The new BBARWA WWTP facilities will be designed for a treatment capacity of 2.2 million gallons per day (MGD). By 2040, accounting for expected growth, it is estimated that the WWTP could produce 2,210 acre-feet per year (AFY) of advanced treated effluent, assuming a 99% total recovery rate could be achieved (90% RO recovery and 90% recovery of brine through brine minimization). Up to 80 AFY of the disinfected, advanced treated effluent will be sent to Shay Pond discharge, and any remaining disinfected, advanced treated effluent will be sent to the Lake discharge. All remaining flows in excess of the new treatment train's 2.2 MGD capacity will continue to be treated to undisinfected secondary standards and conveyed to BBARWA's existing Lucerne Valley site, which is regulated by the Colorado River Basin Regional Water Quality Control Board.

As described in the Technical Memorandum (Attachment B of the ROWD package) titled *Approach to Address Big Bear Lake Nutrient Total Maximum Daily Load in the NPDES Permit for Big Bear Area Regional Wastewater Agency (WSC & LWA, 2022)*, the Agency Team proposes to implement a total phosphorus (TP) Offset Program for the Lake discharge to attain net zero TP loads to the Lake to be consistent with the assumptions of the Big Bear Lake Nutrient Total Maximum

Daily Load (Nutrient TMDL) for Dry Hydrologic Conditions. While a portion of the disinfected, advanced treated effluent is planned for discharge to Shay Pond, the maximum anticipated Lake discharge of 2,210 AFY, coupled with the TP Offset Program in the Lake, is the basis of the antidegradation analysis for the Lake discharge. Modeling analysis has also been conducted to evaluate a range of additional scenarios; these results are presented herein to provide additional information.

The proposed Lake discharge will be physically discharged at the east end of Stanfield Marsh, then flow through the Marsh into the Lake through a set of culverts under Stanfield Cutoff. Due to prolonged drought conditions, Stanfield Marsh has been mostly dry since 2015. Therefore, current ambient water quality data is not available. Additionally, the water quality objectives (WQOs) specified for the Lake in the Water Quality Control Plan for the Santa Ana River Basin (Basin Plan) are more stringent than those for Stanfield Marsh. Therefore, this antidegradation analysis focuses on the impacts to water quality in the Lake.

This antidegradation analysis provides the Santa Ana Regional Water Quality Control Board (Regional Water Board) with the information needed to determine whether the proposed Lake discharge and Shay Pond discharge are consistent with the State of California (State) and federal antidegradation policies.

Note that the Replenish Big Bear Program also includes subsequent uses of Lake water for purposes such as 1) landscape irrigation, construction uses, and snowmaking at the golf course and ski resort and 2) direct groundwater recharge in Sand Canyon. It is anticipated that these uses will be regulated separately and are not discussed in this antidegradation report. Coordination with the California State Water Resources Control Board Division of Drinking Water (DDW) is underway to regulate these recycled water uses.

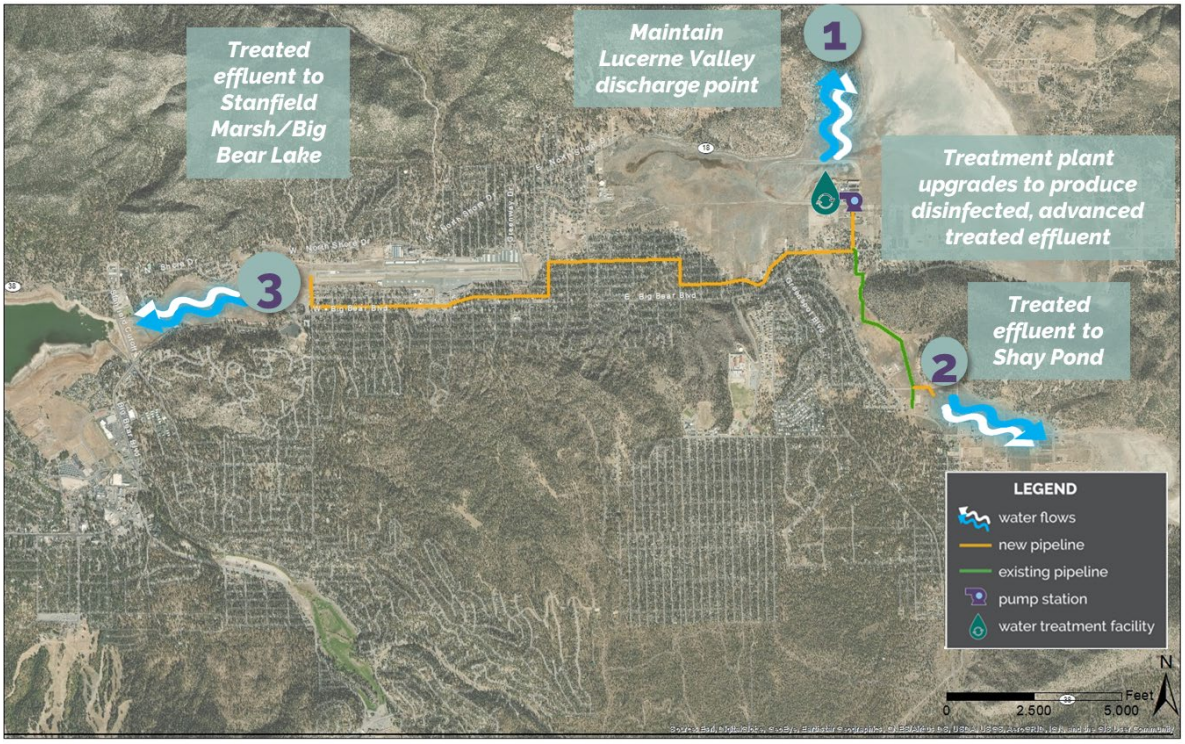

Figure ES - 1. Replenish Big Bear Program Lake and Shay Pond Discharge Locations

Water Quality Impacts of Proposed Discharges

The Replenish Big Bear Program Lake discharge is anticipated to improve Lake water quality for total dissolved solids (TDS), total phosphorus (TP), total nitrogen (TN), and chlorophyll-a as compared to modeled baseline (no project) conditions, and result in similar water quality for total inorganic nitrogen (TIN) as compared to the modeled baseline. In addition, the proposed discharge is anticipated to feature concentrations similar to or lower than ambient water quality and the most stringent WQO or criterion for all constituents evaluated except for boron. For boron, concentrations in the Lake are anticipated to increase as compared to baseline conditions, but remain well below the most stringent WQO of 0.75 mg/L.

The Shay Pond discharge is anticipated to be of better quality than the current potable water supply and ambient water quality for most constituents of interest. However, additional data may be needed to confirm these findings. Like the Lake discharge, boron may be the only constituent in the disinfected, advanced treated effluent discharged to Shay Pond that could be above existing ambient water quality for the constituent. However, it is well below the WQO of 0.75 mg/L that exists for the protection of water used to irrigate boron-sensitive agricultural crops, which is not a use of the water in Shay Pond. Additional coordination with the California Department of Fish and Wildlife (CDFW) will be conducted to ensure the Unarmored Threespine Stickleback (Stickleback) fish, a federally and State listed endangered species, and located in Shay Pond are protected.

Consistency with Antidegradation Policies

The proposed project, the discharge of disinfected, advanced treated BBARWA effluent to (1) Stanfield Marsh/ Lake at a discharge rate up to 2,210 AFY and (2) Shay Pond at a discharge rate up to 80 AFY, is determined to comprise best practicable treatment and control and is consistent with federal and State antidegradation policies for the following reasons:

- The proposed discharge to both Stanfield Marsh/ Lake and Shay Pond will not adversely affect existing or probable beneficial uses of either receiving water or downstream receiving waters, nor will the discharges cause water quality to not meet applicable water quality objectives.
- Overall, the proposed discharge is estimated to improve water quality in the Lake for TDS, TN, TP, and chlorophyll-a, maintain similar water quality for TIN, and have a very minor impact on boron. Future boron concentrations in the Lake are estimated to increase very slightly due to the proposed BBARWA discharge but are estimated to remain well below the 0.75 mg/L Basin Plan objective for boron (see **Table 7** and **Section 5.3.2**). The Lake Analysis shows that projected ambient Lake concentrations of TIN and chlorophyll-a with the proposed discharge will exist below their relevant WQO (TIN) or TMDL target (chlorophyll-a). The Lake Analysis also shows that ambient Lake concentration of TDS and TP with the proposed discharge are estimated to exceed the 175 mg/L TDS WQO and the 35 µg/L TP TMDL target, respectively. However, the modeled baseline (no project) condition is projected to result in Lake concentrations for TDS, TP, TIN, and chlorophyll-a that exceed those concentrations more often than all modeled BBARWA discharge scenarios. Modeled results for the proposed BBARWA discharge, when combined with a TP Offset Program (see Attachment B of the ROWD package), show the greatest improvements to future, ambient Lake concentrations as compared to the modeled baseline (no project) condition.

- Overall, the proposed BBARWA discharge is estimated to have a very minor impact on Shay Pond water quality and Shay Creek water quality downstream of the pond. The proposed project is estimated to potentially cause a very minor increase in boron concentrations in the pond and downstream in Shay Creek, but concentrations are estimated to remain well below the 0.75 mg/L Basin Plan objective for boron. The disinfected, advanced treated effluent proposed for discharge to the pond is anticipated to lower the concentrations of those constituents listed in **Table 13** as compared to existing ambient concentrations that are largely influenced by the groundwater currently discharged by BBCCSD to the pond to maintain water levels for the endangered Stickleback.
- Based on the above, the request to permit a new discharge to both Stanfield Marsh/ Lake and Shay Pond is consistent with federal and State antidegradation policies in that the minor lowering of water quality boron in the Lake (see **Table 7**) and Shay Pond (see **Table 13**) is necessary to accommodate important economic or social development[1], will not unreasonably affect beneficial uses, will not cause further exceedances of applicable WQOs, and is consistent with the maximum benefit to the people of the State.
- Based on the above, the request to permit new discharges to Stanfield Marsh/ Lake and Shay Pond are consistent with the Porter-Cologne Act in that the resulting water quality will constitute the highest water quality that is reasonable, considering all demands placed on the waters, economic and social considerations, and other public interest factors.

The proposed discharge of disinfected, advanced treated BBARWA effluent to Stanfield Marsh/ Lake and Shay Pond also fully supports California's *Recycled Water Policy* (SWRCB, 2013) in that it would result in an increased use of recycled water from municipal wastewater sources, would incrementally reduce reliance on the vagaries of annual precipitation, and would assist in the sustainable management of surface and groundwater resources.

[1] Maintain and improve recreation and tourism in the Big Bear Lake region which in turn stimulates the local and regional economies.

1 INTRODUCTION

This section provides an overview of the Replenish Big Bear Program, description of the proposed discharges to Stanfield Marsh, a tributary of the Lake, and a separate discharge to Shay Pond, a tributary of Shay Creek. This section also discusses the purpose and approach used in this antidegradation analysis report.

1.1 Program Overview

BBARWA is a joint powers authority formed in 1974 to provide centralized wastewater conveyance, treatment, and disposal for the City of Big Bear Lake, representing approximately 47% of the total connections, BBCCSD, representing approximately 48% of the total connections, and County of San Bernardino Service Area 53B (CSA53), representing approximately 5% of the total connections. Each of these member agencies maintains and operates its own wastewater collection system that conveys wastewater to BBARWA's interceptor system for transport to the BBARWA WWTP. The BBARWA service area includes the entire Valley and covers about 79,000 acres. BBARWA owns and operates a regional WWTP to treat the Valley's wastewater and currently discharges undisinfected secondary effluent to Lucerne Valley, which is located outside the Santa Ana Watershed.

The Replenish Big Bear Program is a collaborative regional water resources program being implemented by Agency Team to help protect the Valley and the Santa Ana Watershed from the impacts of drought and variable precipitation through the recovery of this local water resource currently discharged outside of the watershed.

The Replenish Big Bear Program is comprised of three independent projects:

1) Discharge of disinfected, advanced treated effluent to Stanfield Marsh, which is tributary to the Lake, and a separate discharge to Shay Pond;
2) Use of Lake water for purposes such as landscape irrigation of the local golf course, construction uses and snowmaking; and
3) Use of Lake water for groundwater recharge in Sand Canyon.

The first project is the subject of this antidegradation analysis and is foundational to the Replenish Big Bear Program and necessary to enable implementation of the subsequent uses of Lake water. As part of the first project, the BBARWA WWTP will be upgraded to produce disinfected, advanced treated effluent through tertiary filtration using ultrafiltration, and RO treatment with UV disinfection for the proposed discharges to the Lake and Shay Pond.

Although the proposed Lake discharge will be physically discharged at the east end of Stanfield Marsh, then flow through the Marsh into the Lake through a set of culverts under Stanfield Cutoff, this antidegradation analysis was completed for the Lake since Stanfield Marsh has been mostly dry since 2015. Therefore, current ambient water quality data is not available for this antidegradation analysis. Additionally, the WQOs specified for the Lake in the Basin Plan are more stringent than those for Stanfield Marsh.

Figure 1 shows the WWTP and proposed discharge locations, which are components of the first project. The proposed project's two discharge points will allow BBARWA to minimize the discharge of disinfected, advanced treated effluent outside of the watershed. The Lake discharge will increase Lake levels to better support beneficial uses including recreation and habitat, particularly during times of drought. The Shay Pond discharge will replace potable water currently discharged to the waterbody to maintain the water flow through the pond. Up to 80 AFY of disinfected, advanced treated effluent will be sent to Shay Pond, and any remaining disinfected, advanced treated effluent will be sent to the Lake.

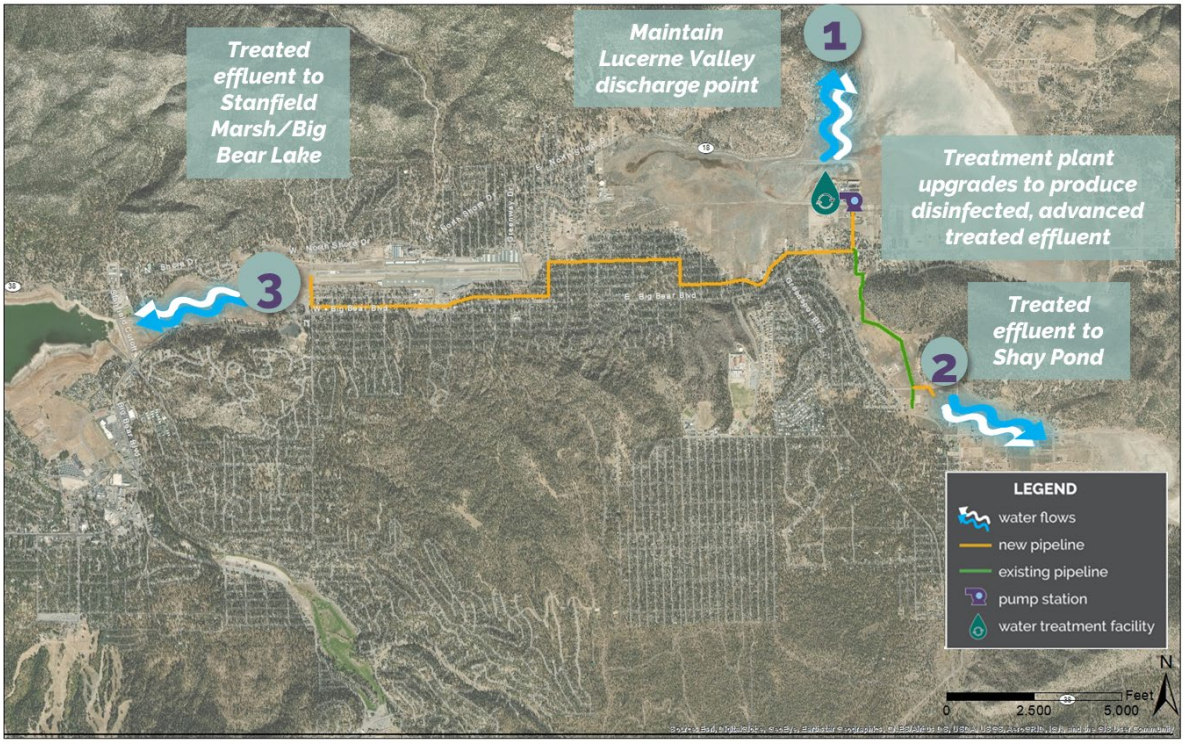

Figure 1. Replenish Big Bear Program Lake and Shay Pond Discharge Locations

The other two projects will utilize Lake water for purposes such as1) landscape irrigation, construction uses, and snowmaking at the ski resort, and 2) direct groundwater recharge in Sand Canyon. **Figure 2** shows the general location of these two projects. The golf course irrigation, construction uses, and snowmaking project can be implemented using existing infrastructure used for snowmaking that draws water from the Lake. The Sand Canyon recharge project will require construction of a pump station, pipeline, recharge ponds and monitoring wells and may be implemented in parallel with the Lake discharge.

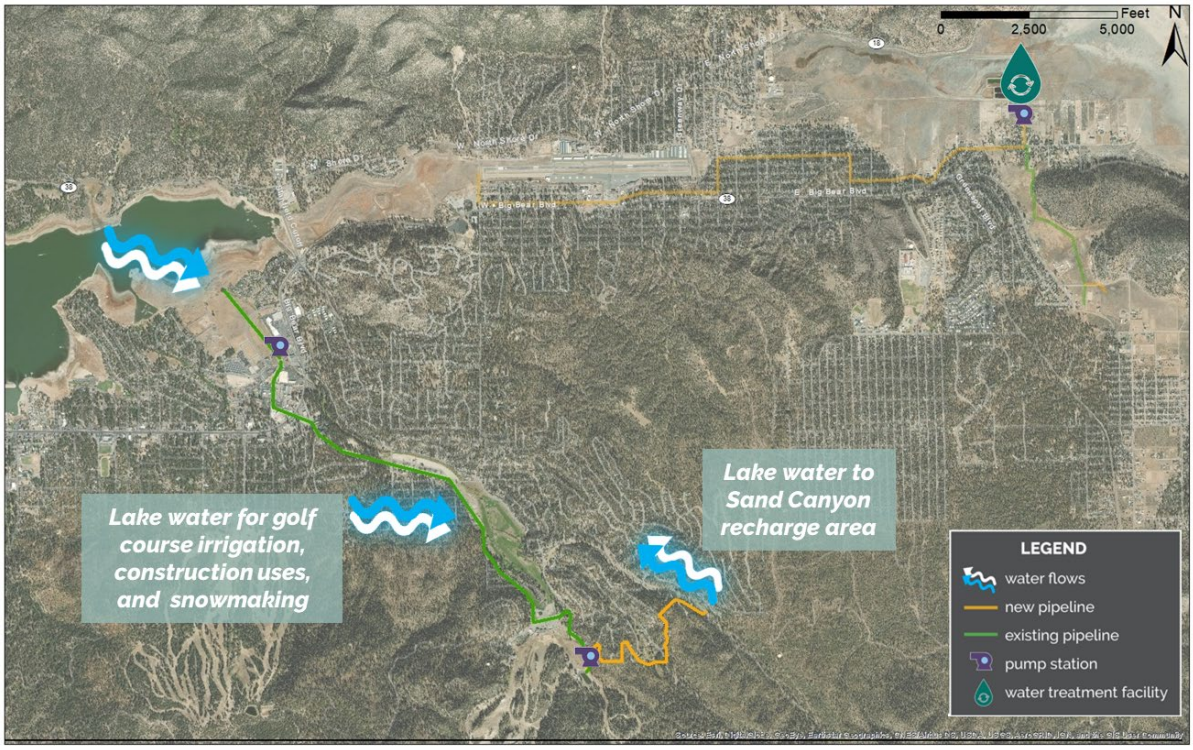

Figure 2. Replenish Big Bear Program Subsequent Uses of Lake Water

1.2 Project Description

The discharge of disinfected, advanced treated effluent to Stanfield Marsh, which is tributary to the Lake, and a separate discharge to Shay Pond is the subject of this antidegradation analysis. The proposed discharges require the construction of WWTP upgrades, an effluent booster pump station at the WWTP site and approximately seven (7) miles of pipeline to convey water to the discharge locations.

Figure 3 shows a process flow diagram of the existing BBARWA WWTP treatment process.

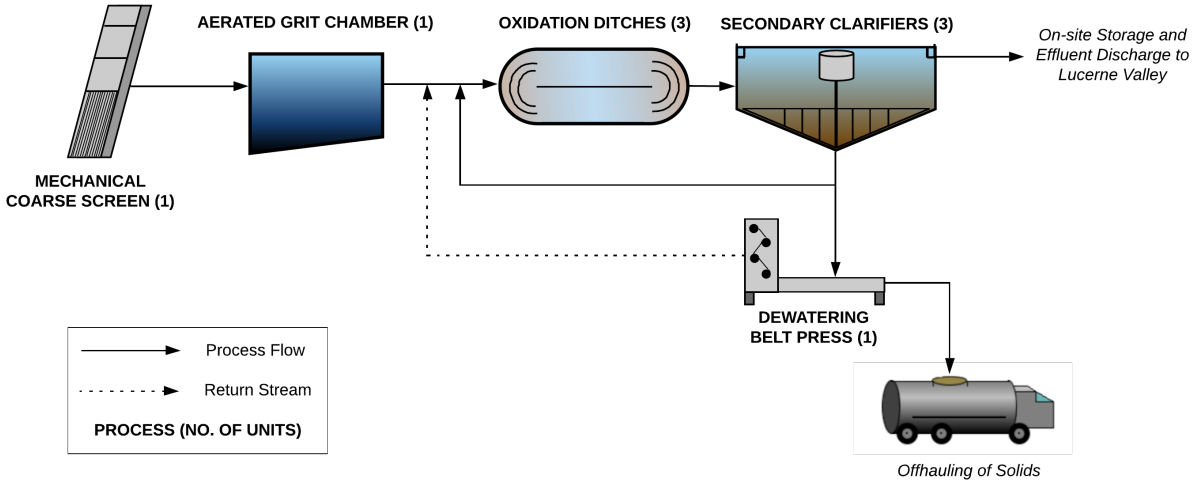

Figure 3. BBARWA Existing WWTP Process Flow Diagram

The existing BBARWA WWTP secondary treatment facility has a capacity of 4.89 MGD and a hydraulic capacity of 9.1 MGD. The WWTP treats commercial and domestic wastewater from the City of Big Bear Lake, BBCCSD, and CSA53 collection systems. The existing treatment process includes the following:

- Preliminary treatment consisting of a mechanical coarse screen and an aerated grit chamber;
- Secondary treatment consisting of extended aeration oxidation ditches and secondary clarifiers; and
- Solids handling through a dewatering belt filter press.

Treated effluent is temporarily stored on-site prior to discharge to Lucerne Valley and dewatered solids are hauled off-site. The undisinfected secondary effluent discharged to Lucerne Valley is currently used to irrigate crops used for livestock feed. This discharge is regulated under Order R7-2021-0023 Waste Discharge Requirements (WDR) permit, issued by the Colorado River Basin Regional Water Quality Control Board (**Appendix A**).

The proposed upgrades, as shown in **Figure 4**, to the BBARWA WWTP to produce disinfected, advanced treated effluent include:

- Biological nutrient removal improvements to the existing oxidation ditches for improved nitrification and denitrification;
- Tertiary filtration and nitrogen and phosphorus removal via denitrification filters;

- Low- and high-pressure filtration with ultrafiltration (UF) membranes and 90% recovery RO membranes;
- Brine pellet reactor for brine minimization to produce a total system recovery of 99%; and
- UV disinfection.

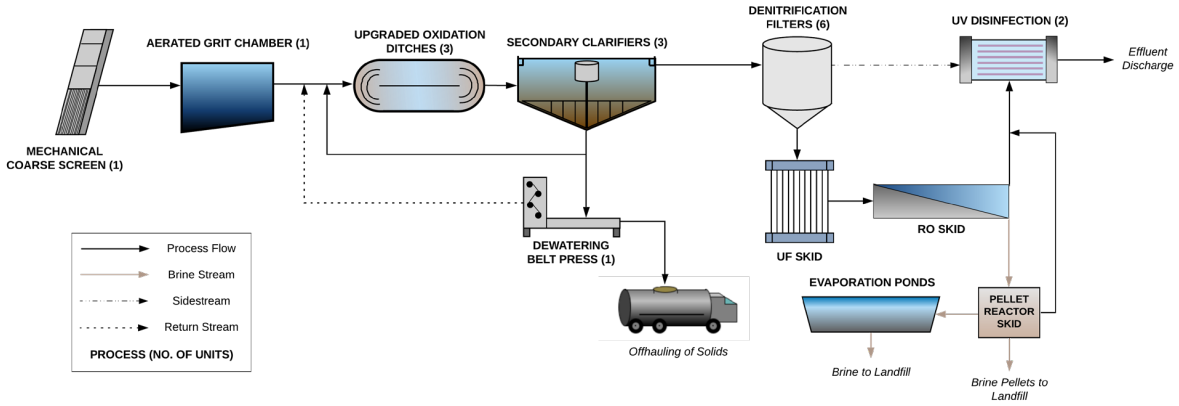

Figure 4. BBARWA Proposed WWTP Treatment Upgrades Flow Diagram

The proposed upgrades (i.e., new advanced treatment train) would be designed for a treatment capacity of 2.2 MGD. By 2040, accounting for expected growth, it is estimated that the WWTP could produce 2,210 AFY of advanced treated effluent, assuming a 99% total recovery rate could be achieved (90% RO recovery and 90% recovery of brine through brine minimization). The WWTP currently produces about 2.0 MGD of undisinfected secondary effluent on an average annual basis.

The RO brine management option included in the preliminary design for Replenish Big Bear is a brine minimization pellet reactor to reduce the volume of brine produced by the RO process. The reduced brine stream from the pellet reactor will be conveyed to evaporation ponds located on BBARWA WWTP property. It is assumed that an RO recovery of 90% at 2.2 MGD influent flow would result in 0.22 MGD of RO brine to be minimized through the pellet reactor and approximately 0.022 MGD of liquid brine to be conveyed to the evaporation pond based on a pellet reactor recovery of 90%. A total evaporation pond area of 23 acres is needed for the brine stream. The RO brine management strategy will be evaluated further as the Project enters the design phase, along with refinements to total system recoveries based on site-specific piloting results.

BBARWA also plans to maintain the existing Lucerne Valley discharge location. All WWTP process water in excess of the new treatment train's 2.2 MGD capacity will continue to be treated to undisinfected secondary levels and conveyed to the existing Lucerne Valley site, consistent with the current, permitted discharge requirements of the existing BBARWA WWTP.

1.3 Purpose of Report

As required by the Clean Water Act (CWA), the discharge of any pollutant or combination of pollutants to surface waters that are deemed waters of the United States (U.S.), as is the Lake discharge and potentially Shay Pond discharge, must be regulated by a National Pollutant Discharge Elimination System (NPDES) permit. Because the two proposed discharge locations are new discharges to surface waters of the U.S., a NPDES permit governing the proposed discharges must be requested from the Regional Water Board.

Under the State and federal antidegradation policies, the Regional Water Board is required to make a finding regarding the satisfaction of the policies as they pertain to surface water discharges for which the Regional Water Board issues a NPDES permit. The State antidegradation policy, which incorporates the federal antidegradation policy, seeks to maintain the existing high quality of water to the maximum extent possible, and only allows a lowering of water quality if:

- Changes in water quality are consistent with maximum benefit to the people of the state, will not unreasonably affect present and potential beneficial uses, and will not result in water quality lower than applicable standards, and
- Waste discharge requirements for a proposed discharge will result in the best practicable treatment or control of the discharge necessary to assure:
    - No pollution or nuisance; and
    - Highest water quality consistent with maximum benefit to the people of the State.

The purpose of this report is to provide the Regional Water Board with the information needed to determine whether the proposed discharges are consistent with State and federal antidegradation policies. This antidegradation analysis includes assessments of water quality impacts on the receiving waters and downstream receiving waters estimated to result from the proposed project; an evaluation of how these estimated changes in water quality compare to applicable WQO and relevant water quality criteria; how estimated changes in water quality may affect existing or probable beneficial uses; and a finding of consistency with antidegradation policies.

1.4 Analysis Approach

The following antidegradation analysis is tailored to be consistent with federal and State antidegradation policies and the guidance provided in the Administrative Procedures Update (APU) 90-004. Pursuant to the APU guidelines, this analysis follows the provisions for a "simple analysis" and evaluates whether changes in water quality resulting from the proposed new discharges to the Lake and Shay Pond are "*consistent with maximum benefit to the people of the State, will not unreasonably affect uses and will not cause water quality to be less than water quality objectives and that the discharge provides protection of existing in-stream beneficial uses and water quality necessary to protect those uses.*"

In general, the data available for existing secondary effluent quality, projected disinfected advanced treated effluent quality, and ambient water quality were assessed to determine if the proposed future discharge would result in concentrations that exceed existing ambient water quality and/or relevant WQOs or criteria. For constituents anticipated to lead to a lowering of existing ambient water quality or an exceedance of relevant WQOs or criteria, further analysis was conducted.

Additionally, TDS, TIN, TN, TP, and chlorophyll-a were evaluated using a two dimensional (2D) hydrodynamic-water quality model (CE-QUAL-W2) developed for Big Bear Lake by Dr. Michael A. Anderson (Dr. Anderson), a limnologist who has in-depth knowledge of the Lake. The model evaluation was conducted to help select the preferred treatment alternative and assess the impacts of the proposed Lake discharge on constituents of interest. The water quality impacts with and without the proposed project were assessed for three different treatment alternatives as documented in *Big Bear Lake Analysis: Replenish Big Bear* (2021 Lake Model Analysis; **Appendix B**). Additional model updates were recently completed to incorporate additional discharge volume scenarios and seasonal variability and documented in *Replenish Big Bear: Modeling of Higher Flows and with Zero TP Load* (2022 Lake Model Update; **Appendix C**). The model results from both analyses are discussed in this report.

For constituents not able to be evaluated by the CE-QUAL-W2 model, their potential impacts with regard to a lowering of existing ambient water quality and/or the exceedance of relevant WQOs or criteria were assessed using a simple mass balance equation.

2 REGULATORY REQUIREMENTS

This section summarizes the federal and State antidegradation policies considered in this antidegradation analysis.

2.1 Applicable Laws and Policies

The federal Clean Water Act (CWA) requires states to adopt, with United States Environmental Protection Agency (U.S. EPA) approval, water quality standards applicable to all intrastate waters (33 U.S.C. § 1313). U.S. EPA regulations also require state water quality standard submittals to include an antidegradation policy to protect beneficial uses and prevent further degradation of high-quality waters (33 U.S.C. § 1313(d)(4)(B); 40 C.F.R. § 131.12). The State's antidegradation policy is embodied in State Water Resources Control Board (SWRCB) Resolution 68-16.

BBARWA's requested discharge of disinfected, advanced treated effluent to the Lake and to Shay Pond requires the application of WQOs contained in the Basin Plan, as well as criteria promulgated by the U.S. EPA for California waters. Both the federal and State antidegradation policies apply to the proposed surface water discharges of treated effluent to the Lake and to Shay Pond.

2.2 Federal Policies and Guidance

The federal antidegradation policy is designed to protect existing uses and the level of water quality necessary to protect existing uses and provide protection for higher quality and outstanding national water resources. The federal policy directs states to adopt a statewide policy that includes the following primary provisions (40 C.F.R. § 131.12).

1) *Existing in-stream water uses and the level of water quality necessary to protect the existing uses shall be maintained and protected.*

2) *Where the quality of waters exceeds levels necessary to support propagation of fish, shellfish, and wildlife and recreation in and on the water, that quality shall be maintained and protected unless the State finds, after the full satisfaction of the intergovernmental coordination and public participation provisions of the State's continuing planning process, that allowing lower water quality is necessary to accommodate important economic or social development in the area in which the waters are located. In allowing such degradation or lower water quality, the State shall assure water quality adequate to protect existing uses fully. Further, the State shall assure that there shall be achieved the highest statutory and regulatory requirements for all new and existing point sources and all cost effective and reasonable best management practices for nonpoint source control*

3) *Where high quality waters constitute an outstanding National resource, such as water of National and State parks and wildlife refuges and waters of exceptional recreational or ecological significance, that water quality shall be maintained and protected.*

4) *In those cases where potential water quality impairment associated with a thermal discharge is involved, the antidegradation policy and implementing method shall be consistent with Section 316 of the Act.*

Based on guidance developed by the U.S. EPA, Region 9 (Guidance on Implementing the Antidegradation Provisions of 40 C.F.R. § 131.12 (U.S. EPA, 1987)) and guidance issued by SWRCB with regard to application of the Federal Antidegradation Policy (Memorandum from William R. Attwater to Regional Board Executive Officers Federal Antidegradation Policy (Attwater, Oct. 1987)), application of the federal antidegradation policy is triggered by a lowering, or potential lowering, of surface water quality. A proposed increase in the volume of an existing discharge or a new discharge to surface water is typically considered a trigger to the application of the federal antidegradation policy. Because the Project is proposing two new discharges to surface waters, the federal antidegradation policy applies.

Both the Lake and Shay Pond are not designated as outstanding natural resource waters and therefore, the receiving waters are not subject to that portion of the federal policy. The application to other portions of the policy is determined on a constituent-by-constituent basis. For a water body where water quality is not significantly better than needed to meet designated uses, either because it does not meet or it just meets applicable water quality objectives or criteria to protect beneficial uses, a new discharge cannot cause further impairment.

For waters with water quality that is better than necessary to support beneficial uses, the new discharge may not lower water quality unless such lowering is necessary to accommodate important economic or social development. In August 2005, the U.S. EPA issued a memorandum discussing antidegradation reviews and significance thresholds (Memorandum from Ephraim S. King, Director, Office of Science and Technology, U.S. EPA, Office of Water to Water Management Division Directors, Regions 1-10 (August 2005). As discussed in the memorandum, an intent of the policy "is to maintain and protect high quality waters and not to allow for any degradation beyond a *de minimis* level without having made a demonstration, with opportunity for public input, that such lowering is necessary and important." (Memorandum at p. 1). U.S. EPA has determined that the significance threshold of a 10% reduction in available assimilative capacity is "workable and protective in identifying those significant lowering of water quality that should receive a full… antidegradation review, including public participation." (U.S. EPA, 2005). This determination by U.S. EPA is helpful in determining the magnitude of water quality change that is determined to be of significant interest in the antidegradation analysis.

2.3 State Policies and Guidance

2.3.1 Resolution 68-16

The State issued its own antidegradation policy in 1968 to protect and maintain existing water quality in California. The State's Resolution 68-16 is interpreted to incorporate the federal antidegradation policy and satisfies the federal regulation requiring states to adopt their own antidegradation policies. Resolution 68-16 states, in part:

1) *Whenever the existing quality of water is better than the quality established in policies as of the date on which such policies become effective, such existing high quality will be maintained until it has been demonstrated to the State that any change will be consistent with maximum benefit to the people of the State, will not unreasonably affect present and anticipated beneficial uses of such water and will not result in water quality less than that prescribed in the policies.*

2) *Any activity which produces or may produce a waste or increased volume or concentration of waste and which discharges or proposes to discharge to existing high quality water will be required to meet waste discharge requirements which will result in the best practicable treatment or control of the discharge necessary to assure that (a) a pollution or nuisance will not occur and (b) the highest water quality consistent with maximum benefit to the people of the State will be maintained.*

2.3.2 1987 Policy Memorandum

In 1987, SWRCB issued a policy memorandum to the Regional Water Quality Control Boards (Regional Water Boards) to provide guidance on the application of the federal antidegradation policy for State and Regional Water Board actions, including establishing water quality objectives, issuing NPDES permits, and adopting waivers and exceptions to water quality objectives or control measures (Attwater, 1987). In conducting these actions, the Regional Water Boards must assure protection of existing beneficial uses, that significant lowering of water quality is necessary to accommodate important economic or social development, and that outstanding national resource waters be maintained and protected. The 2005 U.S. EPA guidance referenced in the Federal Policies and Guidance Section above is useful in determining whether changes in water quality that may result from a proposed action are significant.

2.3.3 Administrative Procedures Update (APU) 90-004

SWRCB issued guidance (APU 90-004) to all Regional Water Boards in 1990 regarding the implementation of State and federal antidegradation policies in NPDES permits. By using this guidance, Regional Water Boards are to determine if a proposed discharge is consistent with the intent and purpose of the State and federal antidegradation policies. APU 90-004 provides Regional Water Boards with guidance on the appropriate level of analysis that may be necessary, distinguishing between the need for a "simple" antidegradation analysis and a "complete" antidegradation analysis. If it is determined that a simple analysis is not appropriate based on the estimated level of impact of the new discharge, then a more rigorous analysis – a complete analysis – is appropriate. A primary focus of the complete analysis is the determination of whether and the degree to which water quality is lowered as compared to the socioeconomic costs of maintaining existing water quality. This determination greatly influences the level of analysis required and the level of scrutiny applied to the "balancing test" – that is, whether the discharge is necessary to accommodate important economic and social development, and whether a water quality change is consistent with the maximum benefit to the people of the State.

The antidegradation analysis addresses the following questions stated in SWRCB APU 90-004 to maintain consistency with State and federal antidegradation policies.

- Whether a reduction in water quality will be spatially localized or limited with respect to the water body; e.g., confined to the mixing zone;
- Whether the proposed discharge of treated effluent will produce minor effects which will not result in a significant reduction of water quality;

- Whether the proposed discharge of treated effluent has been approved in a General Plan, or similar growth and development policy document, and has been adequately subjected to the environmental analysis required in an environmental impact report (EIR) required under the California Environmental Quality Act (CEQA); and
- Whether the proposed Project is consistent with maximum benefit to the people of the State.

The Replenish Big Bear Program seeks to discharge highly treated effluent receiving RO treatment and UV disinfection to the Lake and to Shay Pond. BBARWA has reviewed the NPDES guidance issued by SWRCB in APU 90-004 and believes that the proposed project meets the criteria for a simple antidegradation analysis. The following sections provide the rationale for this determination and an associated level of analysis and information for use by the Regional Water Board in its consideration of state and federal antidegradation requirements in accordance with APU 90-004.

3 APPLICABLE WATER QUALITY STANDARDS

This section summarizes the applicable water quality standards for Stanfield Marsh and the Lake. Stanfield Marsh and the Lake are both waters of U.S., which have several designated beneficial uses. Water quality standard applicable to Shay Pond are discussed in **Section 6**. **Figure 5** shows the proposed discharge location in reference to Stanfield Marsh and Lake.

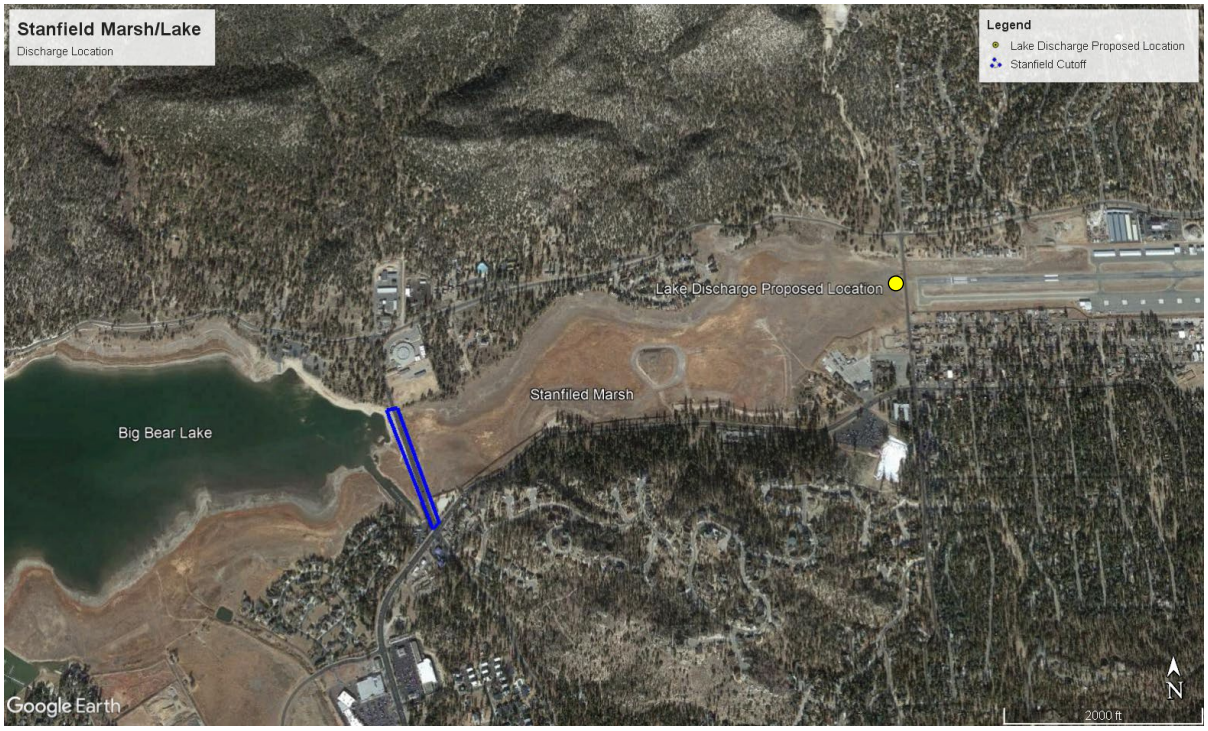

Figure 5. Overview of Lake Discharge Location in Reference to Stanfield Marsh/Lake

3.1 Beneficial Uses

The Basin Plan contains descriptions of the legal, technical, and programmatic bases for water quality regulation in the Santa Ana region. The Basin Plan describes the beneficial uses of major surface waters and their tributaries and the corresponding WQOs put into effect to protect these beneficial uses. **Table 1** shows the designated beneficial uses of the Lake and Stanfield Marsh.

Table 1. Beneficial Uses of Lake and Stanfield Marsh

Beneficial Uses	Big Bear Lake	Stanfield Marsh
AGR - Agricultural Supply	✓	
COLD - Cold Freshwater Habitat	✓	✓
GWR - Groundwater Recharge	✓	
MUN - Municipal and Domestic Supply	✓	✓
RARE - Rare, Threatened, or Endangered Species	✓	✓
REC1 - Water Contact Recreation	✓	✓
REC2 - Non-Contact Water Recreation	✓	✓
SPWN - Spawning, Reproduction, and/or Early Development	✓	
WARM - Warm Freshwater Habitat	✓	
WILD - Wildlife Habitat	✓	✓

3.2 Water Quality Objectives/Water Quality Criteria

To protect the designated beneficial uses, the Regional Water Board applies WQOs contained in the Basin Plan and criteria adopted in the California Toxics Rule (CTR) and the National Toxics Rule (NTR) to the receiving water (i.e., Lake) and downstream receiving waters (i.e., Bear Creek and subsequently Santa Ana River Reach 6). Per the Basin Plan, Stanfield Marsh does not have numeric WQOs. The Lake WQO objectives were used since these are more stringent and the Stanfield Marsh has been mostly dry since 2015.

The Regional Water Board uses these standards to determine if a proposed project will cause or contribute to impairments of the designated beneficial uses. **Table 2** presents the most conservative water quality criteria used to protect the most sensitive beneficial uses that apply to the Lake and downstream receiving waters. The constituents of interest included in **Table 2** are those:

- Included in the Basin Plan;
- Listed in the California 2018 Integrated Report for CWA Section 303(d) list;
- Identified by the Regional Water Board as pollutants of particular concern; and

- Constituents for which a Total Maximum Daily Load (TMDL) exists.

Table 2. Applicable WQOs and/or Criteria for the Lake Discharge

Constituent	Most Stringent WQO or Criterion	Unit	Reference for Most Stringent WQO or Criterion
Ammonia as N	0.46	mg/L	Basin Plan; used Basin Plan Table 4-4 (a)
Boron, Total	0.75	mg/L	Basin Plan(b)
Chloride	10	mg/L	Basin Plan
Fluoride	0.9	mg/L	Basin Plan (c)
Hardness, Total (as CaCO3)	125	mg/L	Basin Plan
Methylene Blue-Activated Substances	0.05	mg/L	Basin Plan (d)
Sodium	20	mg/L	Basin Plan
Sulfate	10	mg/L	Basin Plan
Total Dissolved Solids	**175**	**mg/L**	**Basin Plan**
Total Inorganic Nitrogen	**0.15**	**mg/L-N**	**Basin Plan**

Chlorophyll-a	**14**	**µg/L**	**Nutrient TMDL**
Total Phosphorus	**35**	**µg/L-P**	**Nutrient TMDL**
Chlordane	0.00057	µg/L	Lake CWA 303(d) List; CTR
4,4'-DDT	0.00059	µg/L	Lake CWA 303(d) List; CTR
PCBs	0.00017	µg/L	Lake CWA 303(d) List; CTR
Cadmium, Dissolved	2.2	µg/L	Santa Ana River Reach 6 CWA 303(d) List (f)
Copper, Dissolved	8.9	µg/L	Santa Ana River Reach 6 CWA 303(d) List (f)
Lead, Dissolved	2.5	µg/L	Santa Ana River Reach 6 CWA 303(d) List (f)
Mercury	10	ng/L	Lake CWA 303(d) List; Statewide Mercury Provisions
Aluminum	200	µg/L	Title 22 MCL (g)
Specific Conductance	700/1,000	µmhos/cm	AGR Beneficial Use Goal (g)

Notes: Bolded constituents were identified as constituents of interest by the Regional Water Board and were modeled in the Lake Analysis (**Appendix B** & **C** and discussed in **Section 5.3.1.**

a) The total ammonia was estimated using the equation presented in Table 4-4 of the Basin Plan. The Lake wide average pH is 8.28 based on the 2009-2019 TMDL data collected. The Lake water temperature ranges between 35 °F (1.8°C) and 70°F (20.7°C). The average Lake water temperature used is 53°F (11.8°C).
b) Boron concentrations shall not exceed 0.75 mg/L in inland surface waters of the region as a result of controllable water quality factors.

Constituent	Most Stringent WQO or Criterion	Unit	Reference for Most Stringent WQO or Criterion
c) Annual average concentration determined based on daily air temperature between 17.7-21.4 °C. d) MBAS concentrations shall not exceed 0.05mg/L in inland surface waters designated MUN as a result of controllable water quality factors. It is a secondary drinking water standard. e) Value is being considering by the Regional Water Board, as potential target. f) California Toxics Rule (CTR) hardness-based criterion continuous concentration (CCC) calculated using a median total hardness value of 99 mg/L calculated from measurements made in the Santa Ana River, Reach 6, upstream of Seven Oaks Dam, 2000-2006. g) Constituent added as it was detected in the secondary effluent and Lake.			

The Basin Plan contains both numeric and narrative objectives for inland surface waters, which were used to evaluate the Lake discharge. For this analysis, some of the narrative objectives were not evaluated for the following reasons:

- Algae, floatable, oil and grease, solids (suspended and settleable), sulfides, and surfactants were not evaluated because the Basin Plan does not specify numeric limits so these parameters could not be compared;
- Chlorine residual because chlorine will not be used for disinfection at the BBARWA WWTP;
- Chemical oxygen demand , dissolved oxygen, pathogen indicator bacteria, radioactivity material, color, temperature, and taste and odor because these are assumed to be non-conservative constituents (i.e., presumed to be destroyed, consumed, biodegraded or transformed through the treatment process or through Stanfield Marsh). The treatment process includes low- and high-pressure membrane systems capable of producing effluent that meets or exceeds the objectives for inland surface waters for these constituents, to be confirmed with site-specific piloting of the treatment process;
- Nitrate as N since the TN value being considered by the Regional Board is more stringent than the recommended 10 mg/L in Basin Plan; and
- pH because the treatment process maintains a neutral pH between 7 and 8 upstream of the reverse osmosis process, and then become slightly acidic downstream of reverse osmosis. Reverse osmosis chemical post-treatment will be employed to adjust the pH to a neutral level such that the effluent is within the numerical objectives for pH. In general, the pH of inland surface waters shall not be raised above 8.5 or depressed below 6.5 as a result of controllable water quality factors.

3.3 303 (d) Listings

Section 303(d) of the CWA requires states to develop lists of water bodies (or segments of water bodies) that will not attain water quality standards after implementation of minimum required levels of treatment by point-source dischargers (i.e., municipalities and industries). Section 303(d) requires states to develop a TMDL for each of the listed pollutant and water body combinations for which there is impairment. A TMDL is the amount of loading that the water body can receive and still meet water quality standards for that pollutant. The TMDL must include an allocation of allowable loadings for both point and non-point sources, with consideration of background loadings and a margin of safety. NPDES permit limitations for listed pollutants must be consistent with allocations identified in adopted TMDLs.

The U.S. EPA approved the California's 2018 Integrated Report for CWA Sections 305 (b) and 303(d) on June 9, 2021 (SWRCB, 2021). This list represents the most current listing of impaired water bodies in the project area and downstream areas. The Lake is included in the California's 2018 Section 303(d) list of impaired water bodies for mercury, nutrients, noxious aquatic plants, dichlorodiphenyltrichloroethane (DDT), chlordane, and polychlorinated biphenyls (PCBs). The Santa Ana River (SAR) Reach 6, which is located about 17 miles downstream from the Lake, is also listed for cadmium, lead, and copper. The potential water quality impacts of the proposed Lake discharge are discussed in **Section 5.**

Table 3 lists the constituents identified in the 2018 303(d) list for the Lake and SAR Reach 6, and their potential sources and proposed TMDL completion dates.

Table 3. 2018 CWA Section 303(d) Listed Constituents

Pollutant/Stressor	Potential Sources	Proposed TMDL Adoption
Lake		
Mercury	Source Unknown	2007
Nutrients	Construction/Land Development	Completed
Noxious aquatic plants	Source Unknown	Completed
DDT	Source Unknown	2027
Chlordane	Source Unknown	2027
PCBs	Source Unknown	2019
Santa Ana River Reach 6		
Cadmium	Source Unknown	2021
Lead	Source Unknown	2021
Copper	Source Unknown	2021

3.4 Lake Nutrient TMDL

The Big Bear Lake Nutrient Total Maximum Daily Load (Nutrient TMDL) for Dry Hydrologic Conditions (Resolution No. R8-2006-0023) was adopted by the Regional Water Board on April 21, 2006 and became effective on September 25, 2007. The Nutrient TMDL includes targets in the Lake for TP, macrophyte coverage, nuisance aquatic vascular plant species, and chlorophyll-a. **Table 4** shows the Nutrient TMDL targets. TP is the only constituent that would be directly discharged and controlled by BBARWA.

Table 4. Nutrient TMDL Numeric Targets for All Hydrologic Conditions

Indicator	Target Value [a][b]
TP Concentration [c]	Annual average no greater than 35 µg/L
Macrophyte Coverage[d]	30-40% on a total lake area basis
Percentage of Nuisance Aquatic Vascular Plant Species[d][e]	95% eradication on a total area basis of Eurasian Water milfoil and any other invasive aquatic plant species
Chlorophyll-a Concentration[e]	Growing season average no greater than 14 µg/L

Source: Basin Plan

Notes:

a) Targets to be attained no later than 2015 (dry hydrological conditions), 2020 (all other conditions)

b) Compliance date for wet and/or average hydrological conditions may change in response to approved TMDLs for wet/average hydrological conditions.

c) Annual average determined by the following methodology: the nutrient data from both the photic composite and discrete bottom samples are averaged by station number and month; a calendar year average is obtained for each sampling location by averaging the average of each month; and finally, the separate annual averages for each location are averaged to determine the lake-wide average.

d) Calculated as a 5-yr running average based on measurements taken at peak macrophyte growth.

e) Growing season is the period from May 1 through October 31 of each year. The chlorophyll-a data from the photic samples are averaged by station number and month; a growing season average is obtained for each sampling location by averaging the average of each month; and finally, the separate growing season averages for each location are averaged to determine the lake-wide average.

An analysis to demonstrate that the proposed Lake discharge is consistent with the Nutrient TMDL assumptions is provided in Attachment B of the ROWD package**.** This technical memorandum (TM) also discusses a TP offset framework to address the lack of wasteload allocation (WLA) for the proposed Lake discharge by proposing a TP net zero load. The TM also discusses the effects of the Lake discharge and TP Offset Program on chlorophyll-a, the response target, as documented in the Lake Analysis (**Appendix B**) and new model updates (**Appendix C**).

3.5 Statewide Mercury Provisions

On May 2, 2017, the California State Water Resources Control Board (State Water Board) adopted Resolution 2017-0027, which approved "*Part 2 of the Water Quality Control Plan for Inland Surface Waters, Enclosed Bays, and Estuaries of California—Tribal and Subsistence Fishing Beneficial Uses and Mercury Provisions.*" Resolution 2017-0027 established mercury limits to protect the beneficial uses associated with the consumption of fish by both people and wildlife. For lakes and reservoirs, the mercury water column concentration is to be calculated by the permitting authority (i.e., Regional Water Board). The mercury limit for the Lake has not yet been established. However, the State Water Board is also developing a Statewide Mercury Control Program for Reservoirs that are impaired for mercury. The draft "*2017 Amendment to the Water Quality Control Plan for Inland Surface Waters, Enclosed Bays, and Estuaries of California—Mercury TMDL and Implementation Program for Reservoirs,*" proposes to establish WLAs of 10 ng/L for major WWTPs (permitted flow >1 MGD), and a WLA of 20 ng/L for facilities with no "upstream" dischargers. The Statewide Mercury Provisions identified the Lake as one of the 131 impacted reservoirs. For this analysis, the 10 ng/L WLA was considered for evaluation with respect to potential water quality impacts due to the proposed Lake discharge.

3.6 Title 22 Recycled Water Criteria

Per conversations with DDW, the Lake may be designated as a non-restricted recycled water impoundment and the subsequent use of Lake water for snowmaking, landscape irrigation, construction uses, and groundwater recharge would be subject to recycled water regulations. Additional coordination and studies are being conducted to regulate these uses. It is anticipated that a separate WDR permit will be obtained to regulate the Sand Canyon groundwater recharge project. The non-potable recycled water uses for landscape irrigation, construction uses, snowmaking, and nonrestricted impoundment are anticipated to be regulated under the Statewide Water Reclamation Requirements for Recycled Water Use (Oder WQ 2016-0068-DDW).

4 ENVIRONMENTAL SETTING

This section provides additional context to understand the enviromental setting for the Lake discharge.

4.1 Stanfield Marsh

As part of Replenish Big Bear, the proposed project will discharge to the east end of Stanfield Marsh, then flow into the Lake, as shown in **Figure 5**.

Stanfield Marsh in 2016

Stanfield Marsh is a scenic 145-acre nature park that includes a gazebo, walking paths, and two boardwalks that extend out into the marsh, so visitors can observe the wildlife. Stanfield Marsh is home to rare and diverse species of birds, fish, amphibians, and mammals. Rainfall and snowmelt are the only sources of water for Stanfield Marsh, so the water level varies from season to season. During wet periods, Stanfield Marsh is a thriving wildlife preserve. During extended drought conditions, the water level recedes dramatically, the boardwalks extend over dry soil, and presence of wildlife becomes scarce. In the last 15 years, Stanfield Marsh has been less than half full nearly 40 percent of the time.

4.2 Big Bear Lake

Stanfield Marsh is hydrologically connected to the Lake through a set of culverts under Stanfield Cutoff. The Lake is located about 6,743 feet (ft; 2,055 meters) above mean sea level (MSL) in the San Bernardino Mountains in San Bernardino County. Together, Stanfield Marsh and the Lake have a surface area of approximately 3,000 acres, a storage capacity of 73,320 AF, and an average depth of 32 ft. The Lake's sole source of water is currently snowmelt and stormwater runoff, which are highly variable. The Lake has several sources of water loss including evaporation, water extraction for snow making, dam releases for flood control, fishery protection, and water rights discharges.

The Lake was formed following construction of the Bear Valley Dam in 1883-1884 to serve as an irrigation supply for the citrus industry in the downstream Redlands-San Bernardino communities. BBMWD was formed in 1964 to manage and help stabilize the water level in the Lake. Historically, the Lake was operated as a storage reservoir by the Bear Valley Mutual Water Company (Mutual). However, due to the drastic fluctuations in Lake levels, legal negotiations arising from disagreement between Mutual, BBMWD, and the community of Big Bear Valley regarding water rights and management of the Lake, a 1977 Judgment was established. Under the terms of this court judgment, Mutual retains a storage right and ownership of all water inflow into the Lake. BBMWD is required to provide Mutual with up to 65,000 AF of water from the Lake in a 10-year rolling period.

In 1996, an In-Lieu Agreement was executed that allows BBMWD to maintain higher Lake levels by delivering water to Mutual from an alternate source of water. This alternate source of water, referred to as In-Lieu Water, comes mainly from the State Water Project (SWP) through the San Bernardino Valley Municipal Water District (SBVMWD), a State Water Contractor. Under the In-Lieu Agreement, when the Lake level falls more than 6 foot below full, and during some months when the Lake is between 4 and 6 feet below full, SBVMWD delivers SWP water to meet Mutual's needs instead of BBMWD releasing water from the Lake. BBMWD pays SBVMWD an annual fee that is adjusted each year based on property tax values.

Due to variable precipitation and extended drought, the Lake has experienced drastic changes in water levels, which impact its water quality. In December 2018, the Lake reached a historic low of 18'1" below full, which is less than 40% full by volume. **Figure 6** shows the fluctuation in Lake levels between 2000 and 2021.

The Lake is an important resource that provides extensive recreational, economic, ecological, and aesthetic benefits for the local community as well as the larger inland southern California region. The beneficial uses of the Lake and Marsh are presented in **Table 1**.

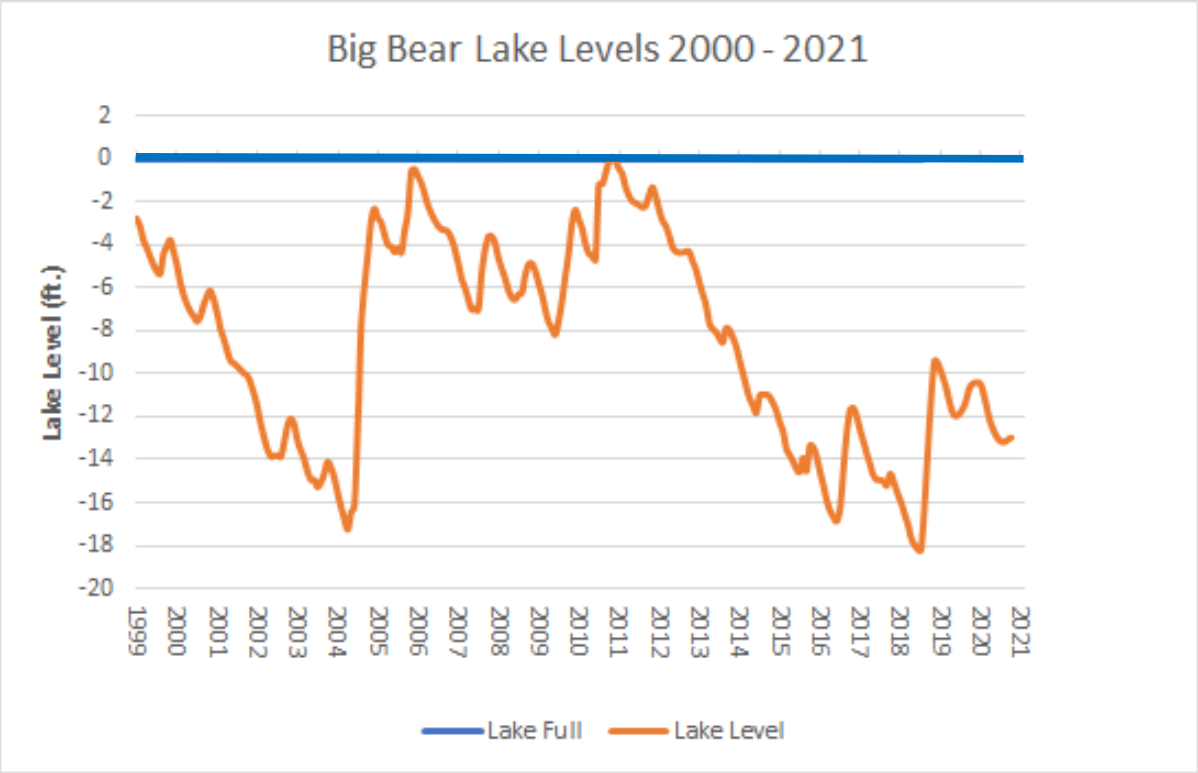

Figure 6. Big Bear Lake Levels: 2000 – 2021

4.3 Santa Ana Watershed

The Lake's dam releases are discharged to Bear Creek, a 17-mile stream, which enters the SAR at Reach 6. The Santa Ana River Watershed comprises portions of San Bernardino, Riverside, Los Angeles, and Orange Counties, covers an area of 2,840 square miles, and is home to over 6 million residents. The Santa Ana River is the major stream draining the watershed—about 100 miles in length from its headwaters near Big Bear to its discharge location in Huntington Beach. **Figure 7** shows the Santa Ana River Watershed, along with the Santa Ana River and its major tributaries.

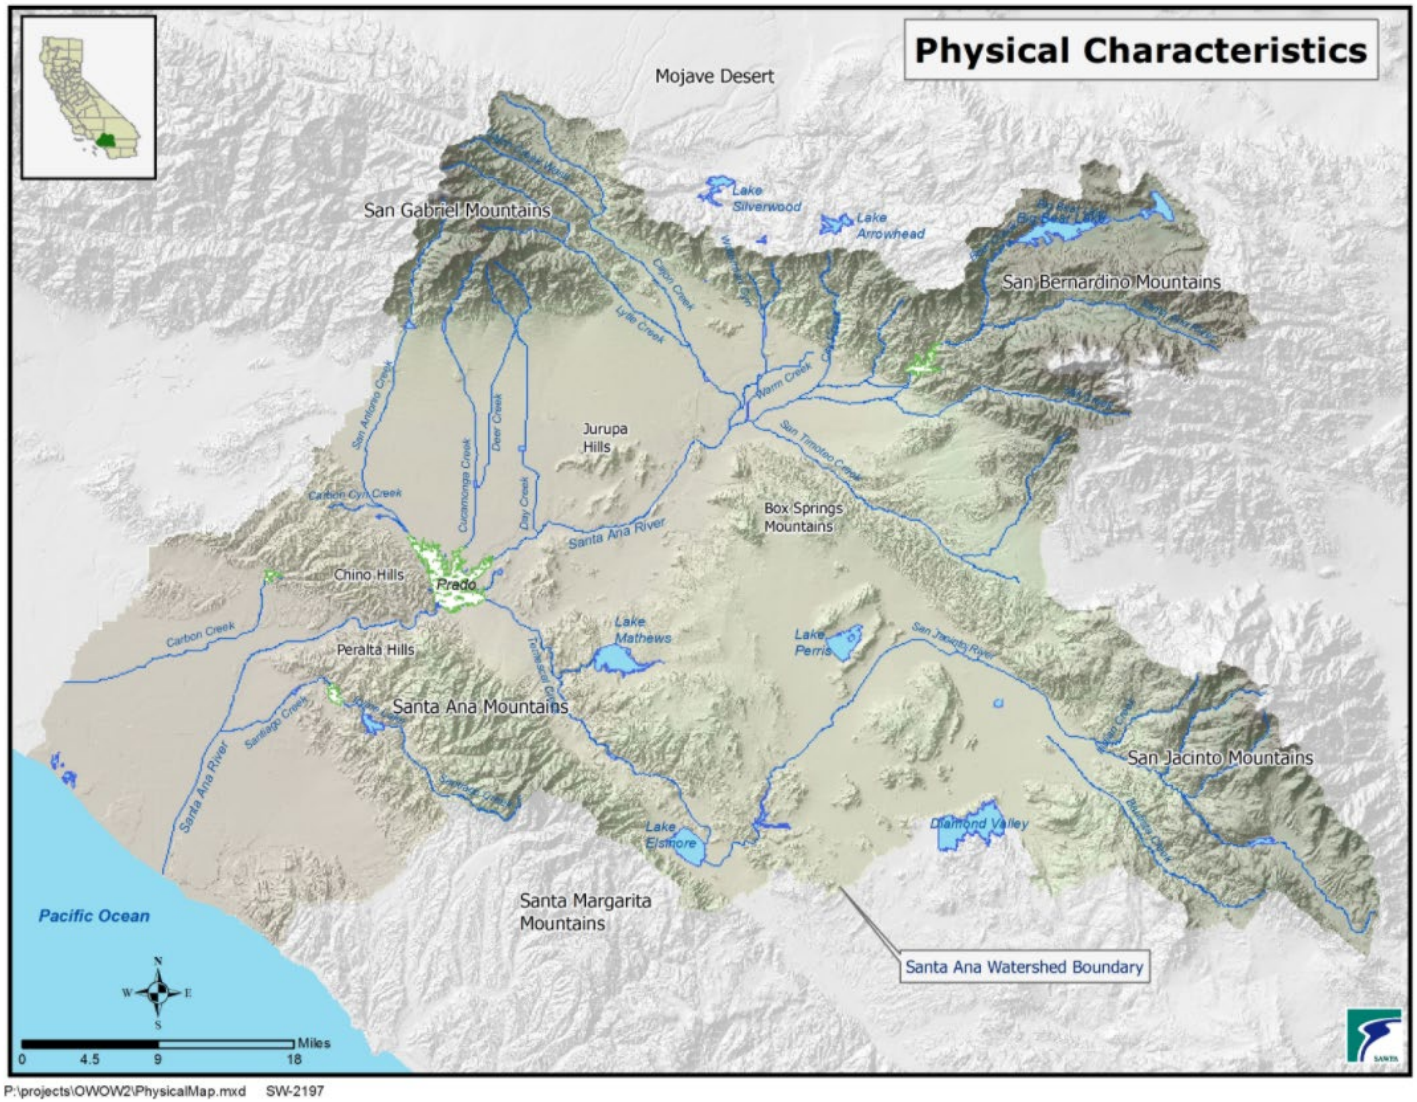

Figure 7. Santa Ana Watershed Map

5 ASSESSMENT OF WATER QUALITY IMPACTS TO BIG BEAR LAKE

This section summarizes the water quality assessment methodology and results for the proposed Lake discharge and potential associated impacts in downstream receiving waters.

5.1 Lake Discharge Project Description

As discussed in **Section 1**, one of the project components of the Replenish Big Bear Program is to discharge to the Lake disinfected, advanced treated effluent that has undergone RO and UV treatment. The Lake discharge is intended to help stabilize Lake levels especially during extended drought periods, assist to maintain the beneficial uses of the Lake, and reduce the in-lieu SWP water demands if higher lake levels allow for additional dam releases. The Lake has experienced record low levels over the last 15 years, forcing BBMWD to close one of their two boat ramps, which reduces the recreational benefit of the Lake.

The projected effluent quality of the proposed discharge is presented in **Table 5** for the constituents of interest in this study (constituents of interest are those listed in **Table 2**). Site-specific pilot testing of the proposed treatment process technologies will be completed in 2023 to establish design criteria and refine final effluent water quality estimates. The values presented in **Table 5** are based on mass balance calculations, vendor provided treatment performance estimates, and industry standard removal rates for RO treatment technology. The secondary effluent data were used as a basis for influent water quality to the advanced treatment train to estimate the projected effluent water quality for the proposed discharge.

Table 5. Projected Effluent Quality of Proposed Discharge and Existing Secondary Effluent Quality

Constituent	BBARWA Secondary Effluent Average Concentrations [a]	Projected Average Effluent Quality of Proposed Discharge	Unit
Ammonia as N	3.15	0.05	mg/L-N
Boron, Total	0.265	0.11	mg/L
Chloride	58	0.60	mg/L
Fluoride	0.41	<0.026[b]	mg/L
Hardness, Total (as CaCO3)	265	3.2	mg/L
Methylene Blue-Activated Substances	0.14	0.0014	mg/L
Sodium	NS	1.9	mg/L
Sulfate	41	0.20	mg/L
Total Dissolved Solids [c]	450	50	mg/L
Total Inorganic Nitrogen [c]	4.40	0.1	mg/L-N
Total Nitrogen [c]	7.80	0.6	mg/L-N
Chlorophyll-a [d]	N/A	N/A	µg/L
Total Phosphorus [c]	2.0	0.03	mg/L-P
Chlordane	<0.17 [e]	<0.17 [b][e]	µg/L
4,4'-DDT	<0.0052 [e]	<0.0052[b] [e]	µg/L
PCBs	<2.5 [e]	<2.5 [b] [e]	µg/L
Cadmium, Total	<0.11	<0.11[b]	µg/L
Copper, Total	14 [f]	0.07	µg/L
Lead, Total	1.3	0.01	µg/L
Mercury, Total	0.76 [g]	<0.5 [b]	ng/L
Aluminum, Total	180	1.3	µg/L
Specific Conductance	755 [e]	18	µmhos/cm

Notes: NS – Not sampled; N/A – Not applicable.

a) The average was estimated using detected values only, unless stated otherwise. NDs were not included due to the limited number of samples. This approach may result in higher averages.
b) The projected effluent quality is anticipated to be below the detection limit. The estimated projected concentration is shows as "<MDL".
c) Values were estimated as part of Draft Treatment Alternatives Analysis TM using BBARWA WWTP average effluent concentrations from weekly and monthly analyses for the 2017 - 2019 calendar years (WSC, 2020).
d) Chlorophyll-a is not a constituent that will be discharged by the BBARWA WWTP.
e) Based on one data point.
f) Values detected below the RL; reported concentration is estimated. Reported as "J-Flag."

Constituent	BBARWA Secondary Effluent Average Concentrations [a]	Projected Average Effluent Quality of Proposed Discharge	Unit
g) On June 18, 2020, BBARWA collected a sample to measure mercury using EPA Method 1631E, which has a reporting limit of 0.5 ng/L. This result is well below the 10 ng/L target described in the Statewide Mercury Control Program for Reservoirs.			

5.2 Selection of Water Quality Constituents

5.2.1 Selection Criteria

As presented in **Section 3**, water quality constituents assessed in this antidegradation analysis were identified based on one or more of the following conditions being satisfied:

1) Constituent has a WQO or criterion applicable to the Lake and/or downstream receiving waters;
2) Constituent for which an adopted TMDL exists;
3) Constituent identified as a pollutant/stressor on the 2018 CWA Section 303(d) list for the Lake or downstream of the proposed discharge; and
4) Constituent is a known water quality concern of the Regional Water Board.

Based on the conditions listed above, 22 constituents of interest were initially identified for evaluation and are presented in **Table 2**. The data available for the secondary effluent, proposed discharge effluent quality, and ambient water quality were assessed to determine the type of analysis needed for a given constituent. The following approach was used:

- No further analysis was needed for constituents reported as non-detect (ND) in the secondary effluent and the Lake. It is anticipated that RO treatment will achieve additional removal of these constituents and thus, will further reduce any water quality impacts potentially associated with these constituents.
- For constituents with detected concentrations in the secondary effluent, the proposed discharge water quality was compared to the ambient water quality and most stringent WQO or criterion.
- For the proposed discharge water quality constituents exceeding the ambient water quality or most stringent WQO or criterion, a mass balance analysis was completed.

- For constituents of greater interest to the Regional Water Board, such as TIN, TN, TP, and chlorophyll-a, the 2D hydrodynamic-water quality model (CE-QUAL-W2) developed by Dr. Anderson was used to evaluate the potential impacts of the proposed Lake discharge. A summary of the Lake Analysis (**Appendix B**) report along with the model updates recently completed to incorporate additional discharge volume scenarios and seasonal variability are presented in this report and in **Appendix C**.

5.2.2 Data Sources

Table 6 shows the water quality data used for the analysis. Per BBARWA's current WDR Permit, BBARWA is required to monitor for biological oxygen demand (BOD), total suspended solids (TSS), pH, dissolved oxygen (DO), TDS, sulfate, chloride, fluoride, nitrate as N, TN, E.coli, and volatile organic compounds (VOCs) in the secondary effluent on a monthly or annual basis. To support the preparation of the proposed project's Report of Waste Discharge (ROWD) and this analysis, water samples of the secondary effluent and Lake were collected and analyzed for priority pollutants. BBARWA collected its samples on November 18, 2021, and BBMWD collected the Lake samples on December 2, 2021. On June 18, 2020, BBARWA also collected a secondary effluent sample to measure mercury using EPA Method 1631E, which has a reporting limit of 0.5 ng/L. **Appendix D** contains the BBARWA, Lake, and Shay Pond (discussed in **Section 6**) water quality data.

As part of the Nutrient TMDL, a variety of constituents, including ammonia as N, total hardness, nitrate as N, nitrite as N, total kjeldahl nitrogen (TKN)[2], TP, and chlorophyll-a are collected at the four TMDL monitoring locations (Station 1 Dam, Station 2 Gilner Point, Station 6 Mid Lake Middle, and Station 9 Stanfield Middle. (See **Figure 2** in **Appendix B**). In the Lake Analysis, TIN[3], TN[4], TP, and chlorophyll-a were evaluated using the Nutrient TMDL data from 2009 through 2019. The average results calculated in the Lake Analysis are presented in **Table 6**.

Ammonia and hardness were not modeled in the Lake Analysis because these were not identified as constituents of interest at the time of the model development. For this analysis, the lake-wide annual average was estimated by averaging the four station annual averages consistent with the Nutrient TMDL approach, which consist of averaging the photic and bottom samples for each sampling date. From 2009 through 2019, about 1,280 and 1,180 data points were collected for ammonia and hardness, respectively, at these locations. The calculations are presented in **Appendix E**.

[2] TKN is the sum of organic nitrogen and ammonia.
[3] TIN is the sum of ammonia, nitrate, and nitrite.
[4] TN is defined as the sum of TKN, nitrite, and nitrate.

BBMWD also has manually recorded specific conductance data since 2001 measured at the first 10 to 15 feet below Lake surface. The specific conductance data was used to evaluate TDS in the Lake Analysis as specific conductance can be converted to TDS using a conversion factor that is dependent on the type of minerals and salts dissolved in the Lake. In August 2019, BBMWD collected TDS samples at the four TMDL monitoring locations to compare TDS and specific conductance results and calculated a conversion factor of 1 mg/L of TDS = 0.642 µmhos/cm, which was used in the Lake Analysis model. The Lake TDS average from this report was converted to µmhos/cm using this convention factor.

Table 6. Summary Statistics for Constituents Evaluated in Secondary Effluent and Big Bear Lake

Constituent	Unit	BBARWA Secondary Effluent [a]				Big Bear Lake[a]			
		No. of Samples	% Non-Detected	Avg.[b]	Max.	No. of Samples	% Non-Detected	Avg.[b]	Max.
Ammonia as N	mg/L	24	29%	3.15	22	1,281	33%	0.063 [c]	0.094
Boron, Total	mg/L	2	0%	0.265	0.270	1	0%	0.054 [d]	0.054 [d]
Chloride	mg/L	25	0%	58	63	1	0%	26	26
Fluoride	mg/L	2	0%	0.41	0.52	1	0%	0.41	0.41
Hardness, Total (as CaCO3)	mg/L	2	0%	265	270	1,176	0%	157 [c]	183
MBAS	mg/L	2	50%	0.14	0.14	1	0%	0.058 [d]	0.058 [d]
Sodium	mg/L	0	NS	NS	NS	1	0%	33	33
Sulfate	mg/L	20	0%	41	44	1	0%	18	18
Total Dissolved Solids	mg/L			450 [e]				251 [f]	
Total Inorganic Nitrogen	mg/L			4.40 [e]				0.049 [f]	
Total Nitrogen	mg/L			7.80 [e]				0.948 [f]	
Chlorophyll-a	µg/L			N/A				9.3 [f]	
Total Phosphorus	mg/L			2.00 [d]				0.037 [f]	
Chlordane	µg/L	1	100%	<0.17	<0.17	1	100%	<0.034	<0.034
4,4'-DDT	µg/L	1	100%	<0.0052	<0.0052	1	100%	<0.001	<0.001
PCBs (Aroclors) [g]	µg/L	1	100%	<2.5	<2.5	1	100%	<0.5	<0.5
Cadmium, Total	µg/L	8	100%	<0.11	<0.11	1	100%	<0.11	<0.11
Copper, Total	µg/L	8	88%	14 [d]	14 [d]	1	100%	<6.5	<6.5
Lead, Total	µg/L	8	75%	1.3	1.8 [d]	1	100%	1.8 [d]	1.8 [d]
Mercury, Total	ng/L	8	100%	0.76 [h]	0.76 [h]	2	50%	270	270
Aluminum, Total	µg/L	2	0	180	250	1	0%	58	58
Specific Conductance	µmhos/cm	1	0	755	755			391 [i]	

Notes: Bolded constituents were identified as constituents of interest by the Santa Ana Regional Water Board and were modeled in the Lake Analysis (**Appendix B** & **C**).

NS – Not sampled; N/A – Not applicable.

a) For constituents with only ND data, the method of detection limit (MDL) is shown as "<MDL."
b) The average was estimated using detected values only, unless stated otherwise. NDs were not included due to the limited number of samples. This approach may result in higher averages. For samples with only one data point, the reported value or "<MDL" is presented.
c) The averages and maximums are for the Lake-wide results and were calculated using Nutrient TMDL 2009-2019 data. See **Appendix E** – for estimates. ND were used and assumed to be "MDL/2".
d) Values detected below the RL; reported concentration is estimated. Reported as "J-Flag."
e) Values were estimated as part of Draft Treatment Alternatives Analysis TM using BBARWA WWTP average effluent concentrations from weekly and monthly analyses for the 2017 - 2019 calendar years (WSC, 2020).
f) TDS average was obtained from the Lake Analysis Table 19, and nutrients and chlorophyll-a from the Lake Analysis Table 22 (**Appendix B**).
g) PCBs are a class of chemicals which include Aroclors 1242, 1254, 1221, 1232, 1248, 1260, and 1016. The aquatic life criteria apply to the sum of the set of seven Aroclors. All results were non-detect.
h) On June 18, 2020, BBARWA collected a sample to measure mercury using EPA Method 1631E, which has a reporting limit of 0.5 ng/L. This result is well below the 10 ng/L target described in the Statewide Mercury Control Program for Reservoirs.
i) The Lake TDS average from the Lake Analysis report was converted to µmhos/cm using a 1 mg/L of TDS = 0.642 µmhos/cm conversion factor.

5.2.3 Selection of Constituents

The simple qualitative analysis described in **Section 5.2.1** was applied to the 22 constituents of interest to determine if additional analysis was required. **Table 7** shows the results of the comparison of the secondary effluent quality, projected effluent quality, ambient water quality, and the most stringent WQO or criterion.

Overall, no constituents exceeded their most stringent WQO or criterion and only boron and TIN exceeded existing, ambient water quality concentrations. For the remainder of the constituents—where the projected effluent quality is below the ambient water quality and the most stringent WQO or criterion—no additional analysis was conducted.

The Lake Analysis evaluated TDS, TIN, TN, TP, and chlorophyll-a, so potential TIN water quality impacts were addressed by the Lake Analysis. For boron, a simple mass balance spreadsheet model was used to evaluate the potential impacts of boron on the Lake with the proposed project due to the limited data available.

With respect to the three trace metals – cadmium, copper, and lead – included in the 2018 303(d) list for Reach 6 of the SAR as impairing the water body segment, projected average concentrations of the three trace metals in the proposed discharge are significantly below the hardness-based CTR chronic criterion calculated for each metal using a median total hardness value of 99 mg/L calculated for Reach 6 (see **Table 2**). Cadmium, copper, and lead concentrations contained in the disinfected, advanced treated effluent proposed for discharge to the Lake are not anticipated to lower water quality in Reach 6 for these trace metals, nor are they anticipated to affect future load or WLA included in an adopted TMDL.

Table 7. Comparison of Most Stringent Water Quality Objective or Criterion to Existing Ambient Lake Water Quality and Projected Effluent Quality of Proposed Discharge

Constituent	Unit	Most Stringent WQO or Criterion	Average Lake Concentration [a] [b]	Projected Average Effluent Quality of Proposed Discharge [c]	Comparison of Projected Effluent Quality to Most Stringent WQO (see table Notes)
Ammonia as N	mg/L	0.46	0.063 [d]	0.05	1
Boron, Total	mg/L	0.75	0.054 [e]	0.11	2
Chloride	mg/L	10	26 [e]	0.60	1
Fluoride	mg/L	0.9	0.41 [e]	<0.026	1
Hardness, Total (as CaCO3)	mg/L	125	157 [d]	3.2	1
MBAS	mg/L	0.05	0.058 [e]	0.0014	1
Sodium	mg/L	20	33 [e]	1.9	1
Sulfate	mg/L	10	18 €	0.20	1
Total Dissolved Solids	mg/L	175	251	50	3
Total Inorganic Nitrogen	mg/L	0.15	0.049	0.1	2,3
Total Nitrogen	mg/L	1	0.948	0.6	3
Chlorophyll-a	µg/L	14	9.3	N/A	3
Total Phosphorus	mg/L	0.035	0.037	0.03	3
Chlordane	µg/L	0.00057	<0.034 [e]	<0.17	4
4,4'-DDT	µg/L	0.00059	<0.001 [e]	<0.0052	4
PCBs	µg/L	0.00017	<0.5 [e]	<2.5	4
Cadmium, Total	µg/L	2.2	<0.11 [e]	<0.11	4
Copper, Total	µg/L	8.9	<6.5 [e]	0.07	1
Lead, Total	µg/L	2.5	1.8 [e]	0.01	1
Mercury, Total	ng/L	10	270	<0.5	1
Aluminum, Total	µg/L	200	58 [e]	1.3	1

Constituent	Unit	Most Stringent WQO or Criterion	Average Lake Concentration [a] [b]	Projected Average Effluent Quality of Proposed Discharge [c]	Comparison of Projected Effluent Quality to Most Stringent WQO (see table Notes)
Specific Conductance	µmhos/cm	700/1,000	391	18	1

Notes: Bolded constituents were identified as constituents of interest by the Regional Water Board and were modeled in the Lake Analysis (**Appendix B** & **C**).
N/A – Not applicable.

a) For constituents with only ND data, the method of detection limit (MDL) is shown as "<MDL."
b) The average was estimated using detected values only, unless stated otherwise. NDs were not included due to the limited number of samples. This approach may result in higher averages. For samples with only one data point, the reported value or "<MDL" is presented.
c) If the projected effluent quality is anticipated to be below the detection limit. The estimated projected concentration is shows as "<MDL".
d) The averages and maximums are for the Lake-wide results and were calculated using Nutrient TMDL 2009-2019 data. See **Appendix E** – for estimates. ND were used and assumed to be "MDL/2".
e) Average is based on one data point.

Blue – Projected effluent quality is below the ambient and most stringent WQO or criterion
Red – Projected effluent quality is above the ambient or most stringent WQO or criterion

1) Projected effluent quality is below the ambient and most stringent WQO or criterion. No degradation anticipated.
2) Projected effluent quality is above the ambient, but below the most stringent WQO or criterion. Further analysis needed to determine impacts on water quality.
3) Impacts evaluated in the Lake Analysis (**Appendix B & C**).
4) Secondary effluent and ambient water quality were ND. No further analysis conducted. It is anticipated that RO will achieve additional removal, resulting in even fewer impacts.

5.3 Water Quality Impacts Assessment

5.3.1 Lake Analysis Model Analysis Results

The Lake Analysis (**Appendix B**) was completed to evaluate the short- and long-term impacts of the Lake discharge on lake level, lake area, TDS, TIN, TN, TP, and chlorophyll-a under three different treatment alternatives:

- Alternative 1: TIN & TP Removal
- Alternative 2: 70% RO (in addition to TIN & TP Removal)
- Alternative 3: 100% RO (in addition to TIN & TP Removal)

These treatment alternatives were evaluated under three hydrologic conditions (i.e., extended drought (5th percentile), median (50th percentile), and prolonged above average rainfall (95th percentile)). The model predicted that Alternative 3 would result in a slight improvement in concentrations of TDS, TIN, TN, TP, and chlorophyll-a as compared to modeled baseline conditions. Informed by the results of this study, the 100% RO treatment alternative was selected as the preferred project and the projected effluent quality of Alternative 3 is the focus of this antidegradation analysis.

Additional refinements to the Lake Analysis were completed in 2022, as documented in **Appendix C**, to investigate the impacts of a higher discharge volume, account for WWTP discharge seasonal variability, and assess the impacts of a TP Offset Program as discussed in **Section 3.4** and Attachment B of the ROWD package. The 50th percentile hydrologic scenario for 2009-2050 was used in the updated analysis (i.e., the median hydrologic condition), as it includes a wide array of runoff conditions. All other hydrologic, meteorological, biological, chemical, and sedimentological factors, variables and conditions were identical to those used in prior simulations of long-term future conditions (Anderson, 2021).

The Lake Analysis report assumed a steady annual flow of 1,920 AFY of disinfected, advanced treated effluent discharged to the Lake that excludes the 80 AFY that could be discharged to Shay Pond. However, the proposed Lake discharge may be higher than previously modeled as it did not account for a 99% total recovery rate of BBARWA effluent and potentially a lower discharge rate to Shay Pond. **Table 8** presents the Lake discharge flow projections that were considered in the Lake Analysis model and in the 2022 update.

Table 8. Initial and Updated Lake Discharge Flow Rate Projections

Lake Analysis Modeled Scenario	RBB Inflow (AFY)	Daily RBB Inflow (MGD)
Baseline (No Project)	0	0
Alternative 3 [(a)]	1,920	1.71
High Flow (99% recovery) [(b)]	2,210	1.57 – 2.18
Mid Flow (90% recovery) [(b)]	2,009	1.42 – 1.98

Notes:

a) Alternative 3 was assessed in the 2021 Lake Analysis and assumed that of the total Replenish Big Bear effluent contribution considered in the Lake Analysis (i.e., 2,000 AFY), 80 AFY would be delivered to Shay Pond. Therefore, only 1,920 AFY would be discharged to the Lake.

b) In the 2022 Lake Analysis update it was assumed that no discharge to Shay Pond would occur and all disinfected, advanced treated effluent would be discharged to the Lake under two different total recovery rates scenarios.

The Lake discharge is expected to vary seasonally, as shown in **Figure 8**, and thus, differs from the earlier "Alternative 3" scenario that assumed a uniform flow rate of 1.71 MGD throughout the year. Inflows to the WWTP are lower in the summer months due to reduced inflow and fewer visitors relative to the winter season.

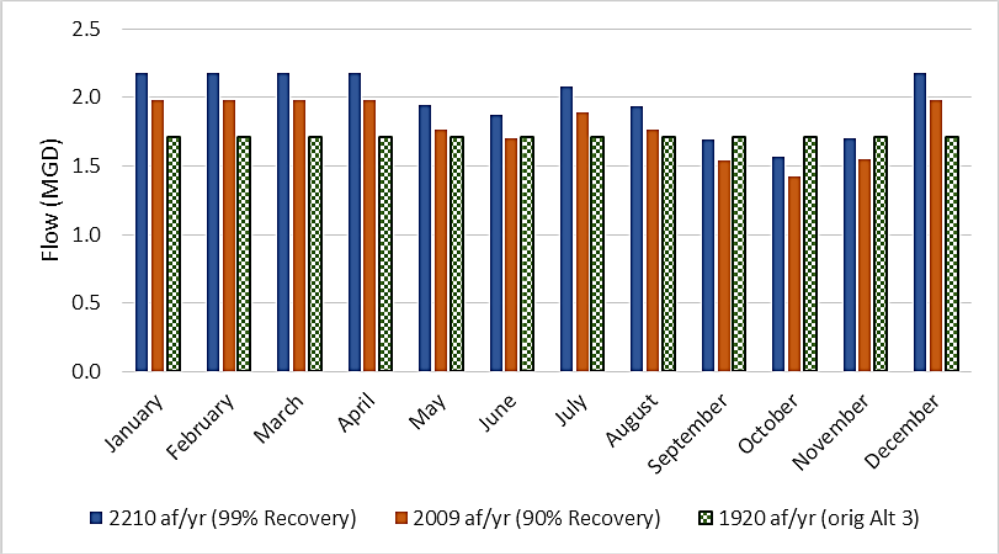

Figure 8. Projected 2040 Monthly BBARWA Discharges to the Lake under Three Inflow Scenarios

Since the Replenish Big Bear Program proposed Lake discharge has not been assigned a WLA for TP in the nutrient TMDL, a TP Offset Program is being proposed to attain a net zero TP contribution to be consistent with the Nutrient TMDL assumptions. A detailed analysis supporting the TP Offset Program is discussed in Attachment B of the ROWD package. In the Lake Analysis model update, the TP offset was modeled as equivalent to a 0 (zero) influent concentration. This approach is a simplification that may hold when considering a whole-lake nutrient budget. However, the Lake dynamics are complex, so projections may not have accounted for these complexities.

5.3.1.1 Lake Discharge Impacts Water Quality

The predicted long-term average water quality in the Lake under the updated modeled operational scenarios (increased and time-varying flows, with and without TP offset) are presented in **Table 9**. For comparison, the previously predicted baseline condition (no project) and Alternative 3 scenario are shown.

Table 9. Predicted Long-term Average Lake Concentrations for TDS, TIN, TN, TP, and Chlorophyll-a Under Different Operational Scenarios

Operational Scenario [a] (All at 50th %tile hydrologic condition)	TDS [b] (mg/L)	TIN [b] (mg/L)	TP [b] (µg/L)	TN [b] (mg/L)	Chlorophyll-a [c] (µg/L)
WQO/(TMDL target)	***175***	***0.15***	***0.15 (35.0)***		***(14.0)***
Baseline (No Project)	195	0.069	47.7	1.15	14.1
Alternative 3 (1920 AFY)	182	0.052	43.3	1.07	14.0
2,210 AFY (99% recovery)	179	0.045	42.3	1.04	13.1
2,009 AFY (90% recovery)	180	0.041	43.4	1.06	12.9
2,210 AFY + TP Offset	179	0.072	39.9	1.00	10.2
2,009 AFY + TP Offset	180	0.040	40.9	1.00	9.5

Notes:

a) The Baseline and Alternative 3 were evaluated in the 2021 Lake Analysis. The other operational scenarios were evaluated in the 2022 Lake Analysis Update and assume no discharge to Shay Pond. The TP Offset scenarios assume a TP Offset Program is implemented.
b) Expressed as annual average concentrations
c) Chlorophyll-a shown as growing season average concentrations

Overall, the predicted long-term average concentrations of TDS, TIN, TN, TP, and chlorophyll-a were lower with the proposed Lake discharge at various rates as compared to the predicted baseline condition, except for TIN under the 2,210 AFY + TP Offset. It is unclear why the model predicted increased TIN under this scenario while all other scenarios showed significantly reduced TIN values relative to the modeled baseline; however, the modeled difference in TIN between the Baseline and 2,210 AFY + TP Offset scenarios is approximately 4%, which is within the range of model variance and is considered statistically insignificant. Therefore, this analysis concludes that projected long-term average concentration of TIN is similar to the modeled baseline condition.

Focusing on chlorophyll-a as the key response target, baseline conditions were predicted to yield a growing season average chlorophyll-a concentration that slightly exceeded (by 0.1 µg/L) the Nutrient TMDL target value of 14 µg/L, while Alternative 3 matched the target value, and increased Lake discharges that varied seasonally (**Figure 8**) yielded values below the modeled baseline condition and the Nutrient TMDL target values. The assumption of a TP Offset Program yielded further reductions in chlorophyll-a. The increased Lake discharge volumes with reduced summer flows and no net TP loading were predicted to yield growing season average chlorophyll-a concentrations as low as 9.5 to 10.2 µg/L, significantly below predicted baseline and TMDL concentrations.

Cumulative distribution functions (CDFs) were prepared to evaluate the inter-annual differences in water quality, as differences are expected to persist. **Figure 9** shows the CDFs for TP, TN, and chlorophyll-a, which show that increased Lake discharges are predicted to lower the annual average TP and TN concentrations and growing season average chlorophyll-a concentrations. However, wide ranges in predicted concentrations remained in place. **Table 10** shows the predicted frequency of exceedance of the Nutrient TMDL targets or potential targets. Overall, the growing season chlorophyll-a average TMDL target (14 µg/L) was predicted to be exceeded about 53% of the time under baseline conditions and exceeded about 41% and 31% of the time at a 2,210 AFY Lake discharge rate with and without TP offset, respectively.

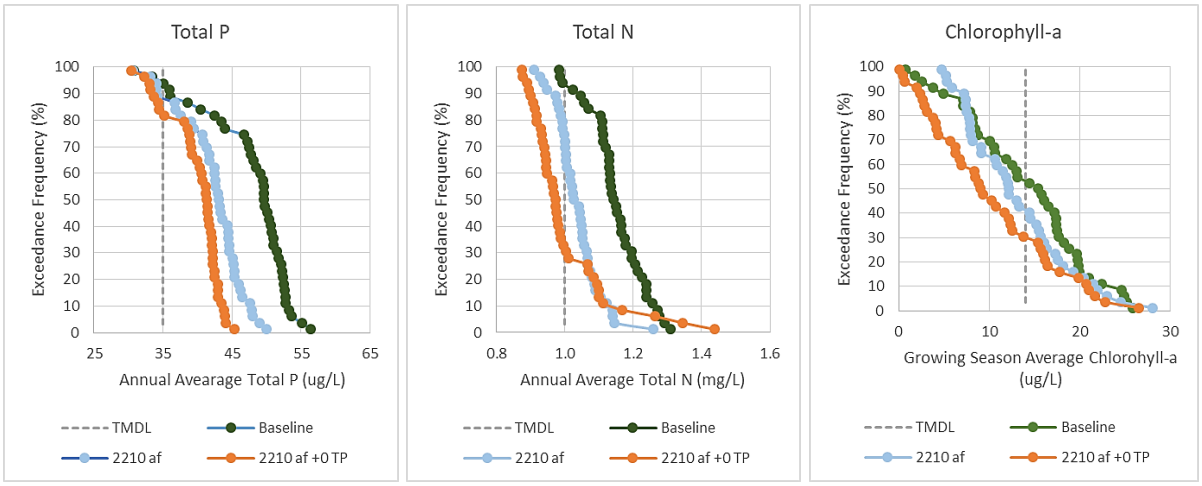

Figure 9. CDFs for Predicted Annual TP and TN Concentrations and Growing Season Average Chlorophyll-a Concentrations for Baseline Condition and at 2,210 AFY Lake Discharge with and without TP Offset

Table 10. Predicted Frequency of Exceeding TMDL Target Under Baseline Conditions and Different Lake Discharge Rates and TP Offset Scenarios (Annual Average or Growing Season Average Basis)

Operational Scenario (All at 50th %tile hydrologic condition)	TP (µg/L)	TN [a] (mg/L)	Chlorophyll-a [b] (µg/L)
WQO/(TMDL target)	***0.15 (35.0)***		***(14.0)***
Baseline (No Project)	94%	91%	53%
Alternative 3 (1920 AFY)	87%	72%	51%
2,210 AFY (99% recovery)	87%	72%	41%
2,009 AFY (90% recovery)	91%	80%	40%
2,210 AFY + TP Offset	82%	30%	31%
2,009 AFY + TP Offset	90%	55%	22%

Notes:
a) Possible target of 1 mg/L, per the Regional Water Board input.
b) Growing season is the period from May 1 through October 31 of each year.

In general, the Lake Analysis demonstrates that the Lake discharge will likely contribute to more frequent attainment of the Nutrient TMDL numeric targets and associated water quality standards, especially when combined with the offset program and actions taken by the TMDL responsible parties to attain the Nutrient TMDL requirements. Additionally, the Lake discharge will increase Lake levels, which will contribute to protection of other beneficial uses and reduce the amount of time critical hydrologic conditions occur in the Lake. A more robust analysis of this Lake discharge on the Nutrient TMDL is provided in Attachment B of the ROWD package.

5.3.1.2 Lake Discharge Impacts on Lake Level, Volume, and Area

The Lake Analysis simulations for the 2009-2019 evaluation period demonstrated that the Replenish Big Bear Program Lake discharge would result in significant increases in predicted lake levels, volumes, and surface areas relative to baseline conditions. Long-term (2009 to 2050) simulations of the proposed Lake discharge under three different hydrologic scenarios indicate that the discharge would be especially beneficial under an "extended drought" scenario where the discharge is predicted to increase the median lake level by more than 10 ft and the median lake area by nearly 600 acres, which in turn would improve recreational access and provide additional Lake habitat as compared to modeled baseline (no project) conditions. The increased lake level and area benefits provided by the Lake discharge would be more modest under the "prolonged above average rainfall" scenario because higher natural inflows would result in higher lake levels. **Table 11** summarizes the projected impacts on Lake level, area, and volume under three hydrologic conditions modeled in the 2021 Lake Analysis.

Table 11. Predicted Lake Level, Area, and Volume under Three Hydrologic Scenarios

Lake Physical Parameter (median values shown)	Scenario	Hydrologic Scenario		
		Extended Drought (5th Percentile)	Median Hydrologic Condition (50th Percentile)	Prolonged Above Average Rainfall (95th Percentile)
Lake Level (ft) (Lake max 6,743 ft)	Baseline	6,722	6,733	6,736
	+Project	6,732 (+10.5)	6,738 (+7.2)	6,740 (+5.2)
Volume (AF)	Baseline	23,400	47,536	54,724
	+Project	45,750 (+22,340)	59,664 (+12,128)	65,204 (+10,480)
Area (acres)	Baseline	1,720	2,328	2,474
	+Project	2,290 (+572)	2,568 (+240)	2,669 (+195)
Notes: Data taken from Table 24 of Lake Analysis report. Assumed a discharge rate of 1,920 AFY. Additional benefit is expected with a higher discharge rate.				

5.3.2 Boron Mass Balance

The projected boron effluent quality of the proposed Lake discharge is anticipated to exceed the Lake ambient water quality (0.054 mg/L – based on one sample collected in December 2021) but remain well below the most stringent criterion of 0.75 mg/L for the protection of sensitive crops. Therefore, the Lake's boron assimilative capacity, defined as the difference between the criterion and the ambient water quality, is 0.694 mg/L (i.e., 0.75 mg/L – 0.054 mg/L).

Due to the limited amount of water quality data available, a simple spreadsheet model was completed to evaluate the contribution of the Lake discharge to boron concentrations in the Lake over time. The calculations are shown in **Appendix F**. The only available data for boron contributions to the Lake from natural inflows is based on boron samples collected in 1972 from several creeks. These data indicated that boron in natural inflows could range between 0.02 and 0.26 mg/L. These results were not used in this analysis due to it high variability, age of the samples, small sample size, and changes in watershed characteristics since the samples were collected.

This analysis did not establish a baseline condition based on ambient water quality; rather, it was assumed that the Lake and natural inflows had a boron concentration of 0 mg/L and the analysis determined the incremental increase of boron in the Lake as result of the Lake discharge.

The 1977-2020 annual inflow and outflow were obtained from the Big Bear Watermaster annual reports and a 43-year simulation was performed based on a repeat of this historic hydrology. The following equations were used to perform the mass balance:

$$Lake\ Storage\ =\ Initial\ Lake\ Storage\ +\ Lake\ Inflows\ -\ Lake\ Outflows$$

$$Lake\ Inflows =\ Lake\ inflows\ from\ precipitation\ and/or\ snowmelt$$

$$Lake\ Outflows\ =\ Spills\ +\ Releases\ +\ Leakage\ +\ Withdrawals\ +\ Evaporation$$

$$Boron\ Mass\ =\ Boron\ in\ Lake\ +\ Boron\ from\ Lake\ Inflow + Boron\ from\ Discharge\ -\ Boron\ from\ Lake\ Outflows$$

$$Boron\ Concentration\ in\ Lake\ (mg/L) = \frac{Boron\ mass\ in\ Lake\ at\ end\ of\ simulation\ year}{Lake\ volume\ at\ end\ \ of\ simulation\ year}$$

Figure 10 shows the projected boron Lake concentrations over the simulation period. The Lake discharge is anticipated to increase boron concentrations over the 44-year simulation, boron is predicted to increase by about 0.065 mg/L. This is less than the 10% assimilative capacity.

The projected incremental increase in boron concentration in the Lake as a result of the project is 0.065 mg/L at the end of the 44-year simulation. The simulation results represent an incremental increase above the current ambient quality, which was 0.054 mg/L based on one sample collected in December 2021. Based on this sample, the estimated total boron concentration in the Lake with the proposed discharge would be below 0.12 mg/L, which is considered safe for agricultural crops like citrus trees that show sensitivity to boron starting at concentrations between 0.5 – 0.75 mg/L (USDA, 1990). The projected boron concentration will remain low compared to the most stringent criterion of 0.75 mg/L which exists in the Basin Plan for the protection of water used to irrigate sensitive crops.

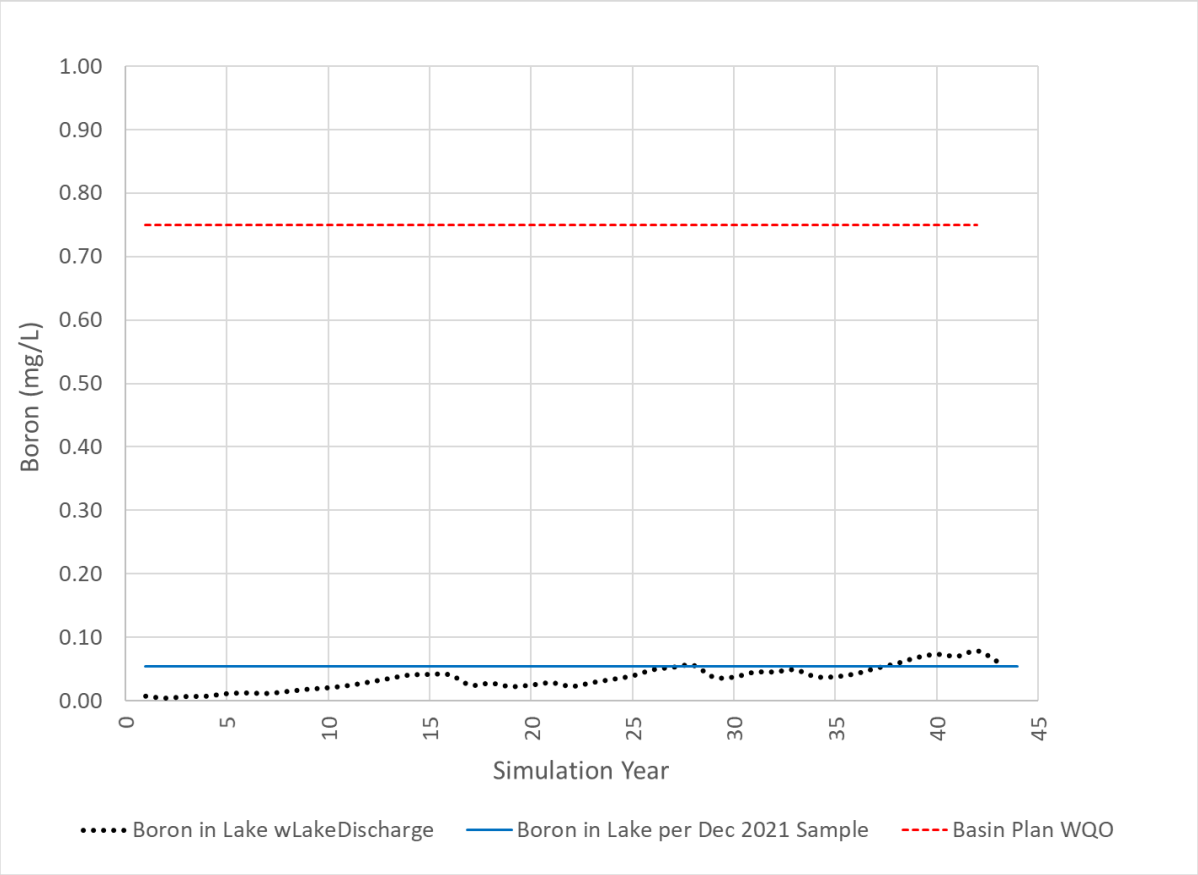

Figure 10. Projected Boron Concentrations with Proposed Lake Discharge

5.4 Summary of Water Quality Impacts

Overall, the Replenish Big Bear Program Lake discharge under most modeled discharge scenarios is anticipated to improve water quality for TDS, TIN, TP, TN, and chlorophyll-a as compared to baseline conditions, and result in similar water quality for total inorganic nitrogen (TIN) as compared to the modeled baseline. In addition, the proposed discharge is projected to contain concentrations of constituents of interest that are similar to or lower than existing ambient water quality and most stringent WQO or criteria for all constituents evaluated except for TIN and boron. For boron, concentrations in the Lake are anticipated to increase compared to baseline conditions but remain well below the most stringent WQO of 0.75 mg/L and the estimated increase is below the U.S. EPA significance threshold of a 10% reduction in available assimilative capacity.

Overall, the Lake Analysis and the 2022 Lake Model Update show that the implementation of the Lake discharge will help improve water quality of the Lake, especially during extended drought and typical (median) conditions. In addition, the proposed Lake discharge will increase lake levels, surface area, and volumes which will help to protect the beneficial uses designated for the Lake.

6 ASSESSMENT OF WATER QUALITY IMPACTS TO SHAY POND

This section describes the proposed Shay Pond discharge component of the Replenish Big Bear Program and presents an antidegradation analysis of the proposed discharge. Currently, it is unknown if Shay Pond and Shay Creek are considered Waters of the U.S. (WOTUS), as the federal regulations that define a WOTUS are currently under review. Regional Water Board input is required to determine the appropriate permitting approach for the proposed discharge to Shay Pond. The necesarry background information to assist the Regional Water Board with this determination is provided in this section.

6.1 Shay Pond Environmental Setting and Project Description

As part of the Replenish Big Bear Program, up to 80 AFY of disinfected, advanced treated effluent is proposed for discharge to Shay Pond. The proposed Shay Pond discharge is intended to replace potable water that is currently discharged to the pond to support the Unarmored Threespine Stickleback (Stickleback) fish, a federal and State listed endangered species.

Shay Pond has a surface area of approximately 10 acres and is located about 1.2 miles southeast of the BBARWA WWTP (**Figure 1**). According to the Bear Valley Basin Groundwater Sustainability Plan (GSP), "*Shay Pond is a natural surface water body at the southern base of an unnamed ridge that separates it from Baldwin Lake (. The nature of this pond is unknown, but it may be fed, in part, from spring flow, surface runoff, and periodically, groundwater intersecting the land surface. Although the pond may have historically been fed from surface water runoff in the ephemeral, upstream segment of Shay Creek, urban development has altered the course of this stream, and it no longer flows into the pond. Surface water exits Shay Pond via the downstream segment of Shay Creek, which flows northwards toward Baldwin Lake and intermittently provides water to Baldwin Lake lake.*" "*Surface water sources to Baldwin Lake are primarily in the form of ephemeral streams with relatively low flow volumes. The only stream where surface water flow periodically has been measured is Shay Creek at its outlet from Shay Pond.*" "*Surface water runoff does not reach Baldwin Lake during most years but percolates into the groundwater system. However, during prolonged precipitation, surface water does flow into Baldwin Lake. All surface water that enters Baldwin Lake is lost to evaporation. The high clay content of the playa sediments prevents vertical migration, and the topographical configuration of the lake prevents outflow from Baldwin Lake*" (TH&Co, 2022). **Figure 11** shows how

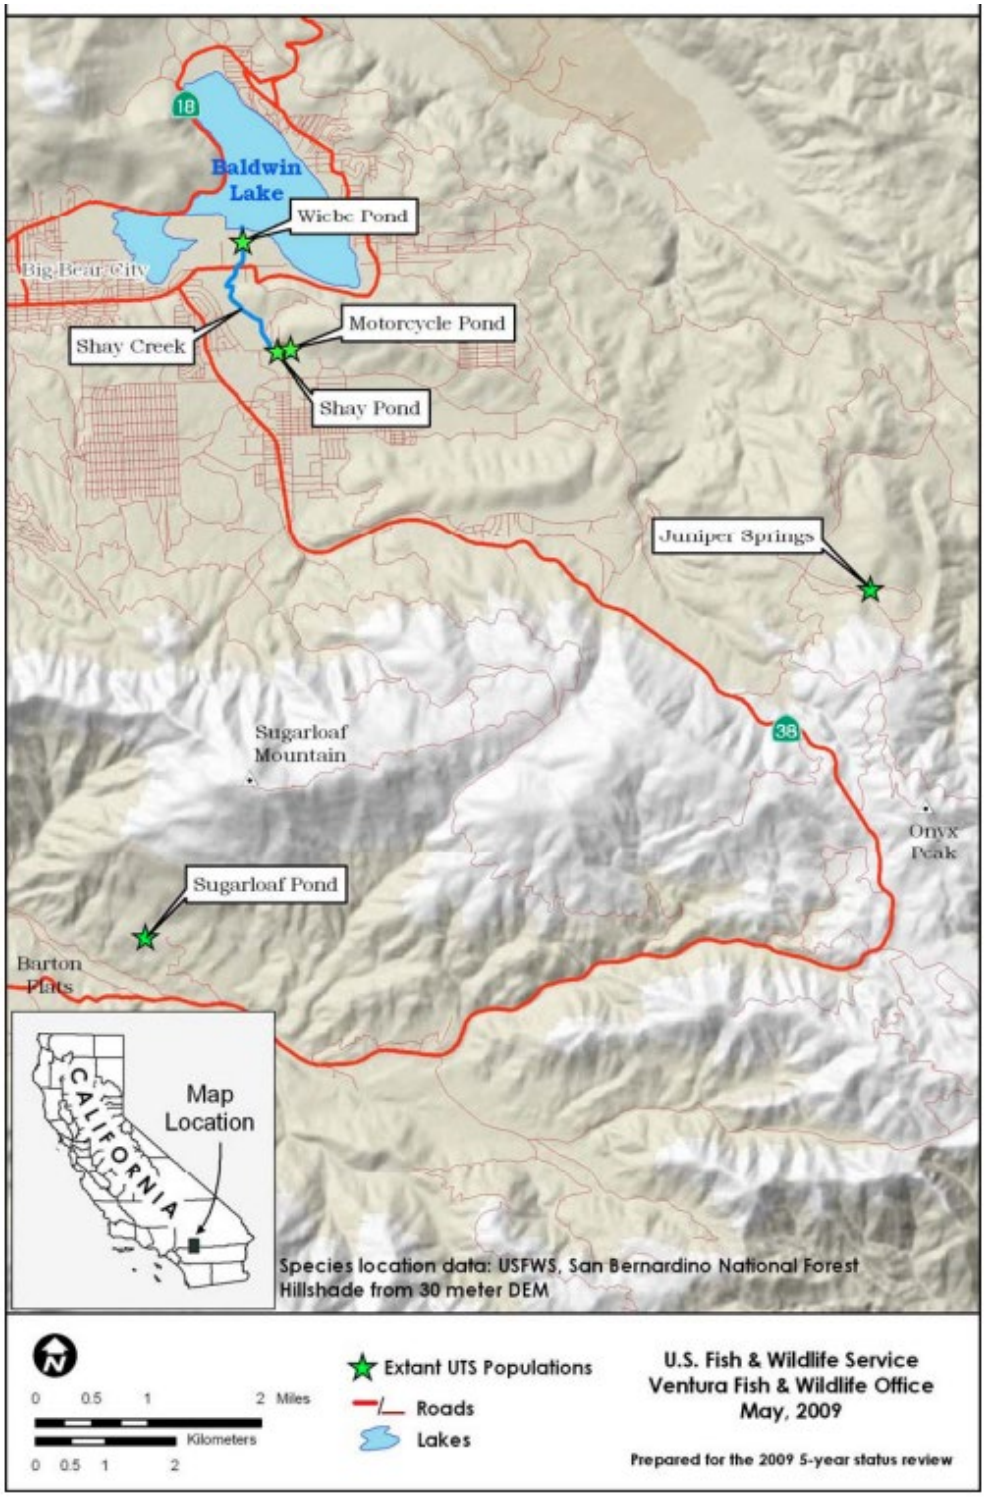
Baldwin Lake, an ephemeral lake, is connected to Shay Pond via Shay Creek. This figure also shows the population of Stickleback fish in the vicinity of Shay Pond.

The population of Stickleback is unique in that it occurs at a high elevation, about 6,700 ft above mean sea level, while all other Stickleback populations inhabit streams below 3,000 ft. In 1985 and 1986, catastrophic mortality of Stickleback in the Valley occurred due to insufficient amounts of water. By the summer of 1990, it was thought that the Stickleback remained in only Shay Pond.

There is a long history of study and group effort regarding the Stickleback in the Shay Creek area. The main stakeholders include the United States Fish and Wildlife Service (USFWS), CDFW, the San Bernardino National Forest (SBNF), BBCCSD, BBLDWP, and BBARWA. Additionally, the Shay Creek Working Group, which includes representatives from the USFWS, CDFW, SBNF, BBCCSD, BBLDWP, and BBARWA, was formed during the process of preparing the USFWS' 2002 Biological Opinion (2002 BO) for the area (Evans, 2002).

The requirements of the 2002 BO state that BBCCSD will provide water to Shay Pond to maintain a minimum 20-gallon-per-minute outflow from Shay Pond. The objective is to maintain a minimum pond water level that will support suitable habitat conditions for the fish. BBCCSD currently meets this requirement by discharging potable water into Shay Pond, but the 2002 BO also states that, should a suitable alternative supply of water be found to be appropriate for the stickleback in the future, BBCCSD may use an 'in-lieu' water supply, which could include the use of tertiary-treated water. The potable water discharged to Shay Pond represents approximately 5% of BBCCSD's customer water demand and could be reserved for potable use instead of discharging to Shay Pond.

The discharge rate needed to maintain the required outflow, accounting for evaoparation and infiltration, has varied from year to year. However, based on the average volume of discharges measured between 2012 and 2020, BBCCSD discharges approximately 50 AFY of potable water to Shay Pond on average. At times, the required discharge has been up to 80 AFY; this maximum volume is used as the basis for the project design and analysis to be conservative. **Figure 12** shows an aerial view of Shay Pond and the proposed discharge location.



(Source: USFWS, 2009)

6.2 Applicable Water Quality Standards

Per the Basin Plan, the protection of beneficial uses designated for Shay Creek and Baldwin Lake is primarily provided by narrative water quality objectives. **Table 12** shows the designated beneficial uses of Shay Creek and Baldwin Lake, which are receiving waters for flows from Shay Pond. Baldwin Lake has intermittent beneficial uses as the lake is ephemeral. The water quality objectives used to protect the beneficial uses designated for Shay Creek and, therefore, Shay Pond are presented in **Table 13**, along with ambient Shay Pond water quality, the quality of the current potable water supply to the pond, and the proposed effluent quality of the proposed discharge.

Table 12. Beneficial Uses of Shay Pond Receiving Waters

Beneficial Uses	Shay Creek	Baldwin Lake
COLD – Cold Freshwater Habitat	✓	I
GWR – Groundwater Recharge	✓	
MUN – Municipal and Domestic Supply	✓	I

Beneficial Uses	Shay Creek	Baldwin Lake
RARE – Rare, Threatened, or Endangered Species	✓	I
REC1 – Water Contact Recreation	✓	I
REC2 – Non-Contact Water Recreation	✓	I
SPWN – Spawning, Reproduction, and/or Early Development	✓	
WARM – Warm Freshwater Habitat		I
WILD – Wildlife Habitat	✓	I
Notes: ✓ - Existing or Potential Beneficial Use; I - Intermittent Beneficial Use		

6.3 Assessment of Water Quality Impacts

The water quality data available for Shay Pond are limited, so a detailed water quality assessment using Shay Pond data could not be completed. For this analysis, the existing water quality of potable water supplies near Shay Pond were compared to the projected effluent quality of the proposed Shay Pond discharge to determine if there is a potential for degradation of Shay Pond water quality as a result of the proposed discharge. The water quality collected in Shay Pond as part of the ROWD application is provided as reference. A similar approach as outlined in **Section 5.2.1** was used to determine if the proposed discharge to Shay Pond could contribute to ambient water quality degradation. **Table 13** presents the results of this analysis.

Water quality data for the specific well that discharges to Shay Pond is not available so the data used for this analysis was obtained by compiling and averaging the water quality data from seven drinking water wells near Shay Pond, which is expected to be representative of the quality of groundwater currently discharged to Shay Pond. BBCCSD collected these data in 2020. The projected effluent quality was estimated as described in **Section 5.1** and presented in **Table 5.** As part of the ROWD process, BBCCSD sampled Shay Pond for 156 constituents, of which only 19 analytes were detected.

Overall, the projected effluent quality of the proposed discharge to Shay Pond is better than the current potable water supply for chloride, hardness, sodium, sulfate, TDS, TN, aluminum, and specific conductance. The projected effluent quality of the proposed discharge is expected to be of similar quality as existing potable water supplies for ammonia, fluoride, MBAS, cadmium, copper, and lead. However, additional data may be needed to confirm these findings. Boron may be the only constituent that could be above the existing potable water supply quality. However, the average boron concentration in the disinfected, advanced treated effluent proposed for discharge to the pond is well below the 0.75 mg/L Basin Plan objective for boron for the protection of sensitive agricultural crops, which is not a use of Shay Pond water.

Additional coordination with the CDFW will be conducted to ensure the Stickleback fish are protected.

Table 13. Comparison of Most Stringent Water Quality Objective or Criterion to Current BBCCSD Potable Water Supply Quality and Projected Effluent Quality of Proposed Discharge

Constituent	Units	Reference for Most Stringent WQO or Criterion	Average Quality of Potable Groundwater Supply [a]	Shay Pond Ambient Quality [b]	Projected Effluent Quality of Proposed Discharge	Comparison of Projected Effluent Quality to Most Stringent WQO (See Table Notes)
Ammonia as N	mg/L	1.4 [c]	NS	0.24	0.05	1
Boron	mg/L	0.75	<0.1	0.059	0.11	2
Chloride	mg/L	500	9	7.6	0.60	1
Fluoride	mg/L	0.9	2.1	1.2	<0.026	1
Hardness, Total (as CaCO3)	mg/L	100	209	180	3.2	1
MBAS	mg/L	0.05	<0.1	<0.1	0.0014	1
Sulfate	mg/L	500	39	23	0.20	1
Total Dissolved Solids	mg/L	1000	291	320	50	1
Total Nitrogen	mg/L-N	10	NS	1.2	0.60	1
Cadmium	µg/L	1.5 [d]	<1	<1	<0.11	1
Copper	µg/L	16.6 [d]	<50	<50	0.07	1
Lead	µg/L	3.5 [d]	<5	<5	0.01	1
Aluminum	µg/L	200	<50	120	1.3	1
Specific Conductance	µmhos/cm	700/1000	496	450	18	1

Notes: NS – Not sampled/no data

a) The average groundwater potable water supply was estimated from 7 domestic wells that were tested and are near Shay Pond. NDs were excluded from the average. Constituents with all ND are reported as "<RL." The MDL was not provided.
b) For Shay Pond, only one sample is available. The results are reported. ND are reported as "<MDL."
c) The total ammonia was estimated using the equation presented in Table 4-4 of the Basin Plan. The field temperature on November 17, 2021, was 56 °F (13.3°C) and pH was 7.7.
d) The cadmium, copper, and lead SSO were estimated using a total hardness value of 180 mg/L, based on the sample collected as Shay Pond.

Constituent	Units	Reference for Most Stringent WQO or Criterion	Average Quality of Potable Groundwater Supply [a]	Shay Pond Ambient Quality [b]	Projected Effluent Quality of Proposed Discharge	Comparison of Projected Effluent Quality to Most Stringent WQO (See Table Notes)

Blue – Projected effluent quality is below the ambient and most stringent WQO or criterion
Red – Projected effluent quality is above the ambient or most stringent WQO or criterion

1) Projected effluent quality is below the ambient and most stringent WQO or criterion. No degradation anticipated.
2) Projected effluent quality is above the ambient, but below the most stringent WQO or criterion. Further analysis needed to determine impacts on water quality.

7 EVALUATION OF CONSISTENCY WITH ANTIDEGRADATION POLICY

The guidelines set by the State Water Board for the antidegradation analysis (APU 90-004) provide direction on evaluating the proposed discharges to Stanfield Marsh/ Lake and Shay Pond by focusing on whether and the degree that water quality is lowered, and by considering whether or not the assumed water quality discharge is consistent with the maximum benefit to the people of the State. In developing the antidegradation analysis, the beneficial uses and relevant water quality objectives and commonly used criteria for the Lake and Shay Pond were considered.

7.1 Benefits of Proposed Project

The proposed discharges of disinfected, advanced treated wastewater to Stanfield Marsh and Shay Pond maximize the use of a local sustainable water supply within the Valley region through the surface water discharge of highly treated wastewater produced by BBARWA to directly benefit the community and environment and support the following beneficial uses in the Lake, Stanfield Marsh, and Shay Pond: AGR (Lake only), COLD, GWR (Lake and Pond), MUN, RARE, REC1, REC2, SPWN (Lake and Pond), WARM (Lake and Pond), and WILD (see **Table 1** and **Table 12** for additional details). The proposed Lake and Shay Pond discharges as part of the Replenish Big Bear Program are anticipated to provide the following benefits:

- A new local drought proof water supply will reduce the Valley's vulnerability to drought, both for the community and the environment.
- A new constant source of water supply to Stanfield Marsh that will provide more stable aquatic and riparian habitat for diverse species and more opportunities for the community to realize the educational and recreational benefits of Stanfield Marsh. The marsh has been mostly dry since 2015 but with the project, the 145-acre marsh area will be at least 50% wetted even during dry years.
- Increased Lake levels will provide more wetted shoreline to enhance aquatic and riparian habitat in the Lake.
- Increased lake levels provide increased opportunities and flexibility for BBMWD to conduct lake management activities, such as weed harvesting to control aquatic macrophytes. Such activities are anticipated to enhance the contact and non-contact recreation in the Lake.

- Increased Lake levels will improve Lake access for boats and personal watercraft and allow for continued use of Lake water for snowmaking in the winter, both of which will act to maintain and enhance tourism, the single largest driver of the Big Bear economy.
    - The number of boat permits sold is directly impacted by Lake levels, and it is anticipated that increased levels will result in the sale of additional boat permits and increased rates of associated recreation and tourism, all of which stimulate the local and regional economies.
    - Visitors in the winter are directly tied to weather conditions and the Resorts' ability to facilitate snow activities by extracting Lake water to make snow when Lake levels are high enough.
    - The Transient Occupancy Tax (TOT) is the second largest revenue source for the City of Big Bear Lake, making up approximately 27% of the general-purpose revenues. Revenue from tourists fluctuate depending on the timing and amount of precipitation the region receives and Lake levels.
    - A strengthened tourist economy is expected to provide additional job growth and stability. Project implementation is estimated to create 3 new permanent positions at the WWTP, 242 temporary construction jobs and 480 indirect jobs.
- Higher Lake levels will result in reduced demand on SWP water, which is used in lieu of Lake water to meet Mutual's water needs when Lake levels are low.
- Increased inflow to the Lake will result in the Lake being full more frequently and will provide BBMWD additional flexibility in optimizing Lake releases to provide new downstream benefits to the Santa Ana Watershed, including increased flows in Bear Creek and the Santa Ana River to support habitat and additional downstream capture of surface water for groundwater recharge.
- The Lake discharge provides opportunities to use of a portion of the Lake water for subsequent uses that provide additional potable water supply and recreational benefits through direct and in-lieu groundwater recharge and enhanced snowmaking capabilities (these uses are anticipated to be permitted separately).

- A new source of high-quality water will be discharged to Shay Pond to support 10 acres of habitat for the federally listed Stickleback. The new source of water enables the potable water currently used for this purpose to be stored in the groundwater basin to enhance water supply sustainability.

7.2 Socioeconomic Considerations

As a result of the project benefits described in **Section 7.1**, the proposed project will act to support important economic and social development in the Valley.

The project proponents are voluntarily committing the resources necessary to construct and operate an advanced wastewater treatment facility to discharge disinfected, RO treated effluent of the quality that could be permitted to be discharged to the Lake as a means to achieve the multiple project benefits described above. The commitment of resources by the project proponents to construct, operate, and maintain the proposed treatment facility will result in increased wastewater fees paid by residents and businesses in the Valley. The capital cost of the proposed facilities required for the Lake and Shay Pond discharges is estimated at $56 M (in 2021 dollars) and the annual operations and maintenance (O&M) costs are estimated at $2.4 M (in 2021 dollars). These capital and O&M expenditures are estimated to result in an increase in wastewater fees of approximately $150-$200 per connection per year.

Increased wastewater fees that would be paid by residents and businesses in the Valley with implementation of the proposed project are not without local and regional economic impacts. The estimated increase in wastewater fees would need to be paid by households and businesses out of their existing household incomes or operations budgets, respectively. In effect, additional wastewater fees would be paid out of funds that are currently available for other purposes. With respect to households, future increased wastewater fees would result in less disposable personal income available to a household for the purchase of other goods and services. Similarly, an increase in annual utility costs for a business could result in one or more of the following: increased costs for the goods and/or services it provides and/or decreased reinvestment in the business. With respect to individual households, increases in utility costs have a disproportionate effect on households at the lowest socioeconomic levels.

While the estimated increase in annual wastewater fees with implementation of the proposed project is not estimated to produce substantial and widespread economic impacts in the Valley, a requirement to add additional wastewater treatment beyond the advanced level of treatment included in the proposed project could trigger substantial and widespread socioeconomic impacts. Furthermore, the project proponents believe that the cost of any additional required wastewater treatment would not produce improvements in receiving

water quality that are proportionate with the cost of additional treatment. The benefits of maintaining existing water quality and mass emissions in the Lake and Shay Pond for the constituents analyzed in this antidegradation analysis are not commensurate with the costs of additional wastewater treatment, beyond what is included in the proposed project, should such treatment be recommended. The small decrease in water quality with respect to the constituents considered in this analysis is unlikely to affect beneficial uses of the Lake, Shay Pond, and downstream receiving waters.

7.3 Consistency with Antidegradation Policies

The proposed project, the discharge of disinfected, advanced treated BBARWA effluent to (1) Stanfield Marsh/Big Bear Lake at a discharge rate up to 2,210 AFY and (2) Shay Pond at a discharge rate up to 80 AFY, is determined to comprise best practicable treatment and control and is consistent with federal and State antidegradation policies for the following reasons:

- The proposed discharge to both Stanfield Marsh/Big Bear Lake and Shay Pond will not adversely affect existing or probable beneficial uses of either receiving water or downstream receiving waters, nor will the discharges cause water quality to not meet applicable water quality objectives.
- Overall, the proposed discharge is estimated to improve water quality in the Lake for TDS, TN, TP, and chlorophyll-a, maintain similar water quality for TIN, and have a very minor impact on boron. Future boron concentrations in the Lake are estimated to increase very slightly (i.e., less than 10% of the available assimilative capacity) due to the proposed BBARWA discharge but are estimated to remain well below the 0.75 mg/L Basin Plan objective for boron (see **Table 7** and **Section 5.3.2**). The Lake Analysis shows that projected ambient Lake concentrations of TIN and chlorophyll-a with the proposed discharge will exist below their relevant water quality objective (TIN) or TMDL target (chlorophyll-a). The Lake Analysis also shows that ambient Lake concentration of TDS and TP with the proposed discharge are estimated to exceed the 175 mg/L TDS objective and the 35 µg/L TP TMDL target, respectively. However, the modeled baseline (no project) condition is projected to result in Lake concentrations for TDS, TP, TIN, and chlorophyll-a that exceed those concentrations more often than all modeled BBARWA discharge scenarios. Modeled results for the proposed BBARWA discharge, when combined with a TP Offset Program (see Attachment B of the ROWD package), show the greatest improvements to future, ambient Lake concentrations as compared to the modeled baseline (no project) condition.

- Overall, the proposed BBARWA discharge is estimated to have a very minor impact on Shay Pond water quality and Shay Creek water quality downstream of the pond. The proposed project is estimated to potentially cause a very minor increase in boron concentrations in the pond and downstream in Shay Creek, but concentrations are estimated to remain well below the 0.75 mg/L Basin Plan objective for boron. The disinfected, advanced treated effluent proposed for discharge to the pond is anticipated to lower the concentrations of those constituents listed in **Table 13** as compared to existing ambient concentrations that are largely influenced by the groundwater currently discharged by BBCCSD to the pond to maintain water levels for the endangered Stickleback fish.
- Based on the above, the request to permit a new discharge to both Stanfield Marsh/Big Bear Lake and Shay Pond is consistent with federal and state antidegradation policies in that the minor lowering of water quality for boron in Big Bear Lake (see **Table 7**) and Shay Pond (see **Table 13**) is necessary to accommodate important economic or social development[5], will not unreasonably affect beneficial uses, will not cause further exceedances of applicable water quality objectives, and is consistent with the maximum benefit to the people of the State.
- Based on the above, the request to permit new discharges to Stanfield Marsh/Big Bear Lake and Shay Pond are consistent with the Porter-Cologne Act in that the resulting water quality will constitute the highest water quality that is reasonable, considering all demands placed on the waters, economic and social considerations, and other public interest factors.

The proposed discharge of disinfected, advanced treated BBARWA effluent to Stanfield Marsh/Big Bear Lake and Shay Pond also fully supports California's *Recycled Water Policy* (SWRCB, 2013) in that it would result in an increased use of recycled water from municipal wastewater sources, would incrementally reduce reliance on the vagaries of annual precipitation, and would assist in the sustainable management of surface and groundwater resources.

[5] Maintain and improve recreation and tourism in the Big Bear Lake region which in turn stimulates the local and regional economies.

Re: Sand Canyon Recharge Evaluation

This Technical Memorandum (TM) presents an evaluation of groundwater recharge potential within Sand Canyon near the City of Big Bear Lake, California (see Figure 1). The evaluation is being conducted as part of a larger study to assess the feasibility of delivering surface water from Big Bear Lake to Sand Canyon using a combination of existing and new pumps and pipeline infrastructure. The water from Big Bear Lake would include treated water stored in the lake from a Big Bear Area Regional Wastewater Agency (BBARWA) treatment plant. Given the source of water, it will be necessary to consider California Division of Drinking Water (DDW) regulations for indirect potable reuse in evaluating the location of recharge within Sand Canyon.

The specific purpose of this evaluation was to consider the following:

1. Given the surface configuration of the Sand Canyon channel and the hydrogeology of the area, how much water can be recharged in Sand Canyon?
2. Where in Sand Canyon would the recharge facilities need to be located in order to meet DDW regulations for subsurface residence time of recharge water prior to extraction?
3. As there is a diluent requirement for recharge of recycled water in surface basins and given that regulations allow for consideration of subsurface underflow as a diluent source, how much natural underflow can be applied to the diluent requirement in Sand Canyon?

Sources of Data

A number of hydrogeological studies have already been conducted in Sand Canyon. These include:

- Geoscience, 1990. Geohydrologic Characteristics and Artificial Recharge Potential of the Sand Canyon Area. Dated December 1990.
- Geoscience, 2002. Results of Drilling, Construction, Testing and Pump Design for the Sheephorn Well. Dated February 1, 2002.

Analysis Methodology

Geoscience (1990) had previously conducted a travel time analysis for the Sand Canyon area using a numerical groundwater flow model. The downgradient extent of recharge ponds was identified as the point where Teton Road crosses the channel (see Figure 2). Based on this analysis, the travel time to the proposed downgradient extraction wells (proposed to be near TH-5) was more than six months. However, the analysis was based on a range of assumed hydraulic conductivity of 13 ft/day to 40 ft/day. Further, the range of effective porosity was 0.15 to 0.2. These values are relatively high and estimated based on the lithology of sediments encountered during drilling of test boreholes in the area. Subsequent pumping tests from the City of Big Bear Lake Department of Water's (the City's) Sheephorn Well (see Figure 2) indicate that the hydraulic conductivity of the aquifer is less than 1 ft/day. Further, other pumping tests in the area have shown that the effective porosity (which is equivalent to the specific yield in an unconfined aquifer) is on the order of 0.04.

In order to reevaluate the potential travel time and mounding from recharge basins upstream of Teton Road using updated aquifer properties, TH&Co developed a two-dimensional analytical flow model of the Sand Canyon area (see Figure 3 for model area). The analysis was conducted for steady state conditions using the model code WinFlow[1]. All travel time analyses were conducted using the particle tracking feature which allows for the estimation of groundwater travel time between two points from advective groundwater flow. The analysis incorporated the following assumptions:

- The area of the Sand Canyon channel identified for recharge is shown on Figure 3 and is equivalent to approximately 4.2 acres.
- The volume of water applied to the Sand Canyon recharge area was based on an assumed recharge rate of 0.5 ft/day, applied to the recharge basins over a 6-month period. Thus, the total volume of managed recharge for the simulation was 384 acre-ft.

[1] WinFlow Version 3, Environmental Simulations Inc., 2003.

- The analysis was conducted with the Sheephorn Well pumping at a rate of 125 gallons per minute (gpm) for 7 hours per day and the Sand Canyon Well pumping at a rate of 115 gpm for 9 hours per day.
- The initial groundwater levels were conditioned to a groundwater level contour map published by Geoscience (1990)[2] (see Figure 3). This contour map was generated based on data collected during a relatively dry hydrologic period.
- The hydraulic conductivity of the aquifer beneath the basins is assumed to be 1 ft/day.
- The porosity of the aquifer sediments is assumed to be 0.04.
- The sediments in the vadose zone and aquifer are homogeneous.

Findings

Recharge Potential

The primary limit to recharge rates in the Sand Canyon area appears to be available subsurface storage space to accommodate the groundwater mound. The target maximum groundwater level relative to the land surface was 20 ft below ground surface. Previous studies in the Big Bear area have shown that this depth is protective of liquefaction. This groundwater level was achieved at a recharge rate of 2.1 acre-ft/day in the recharge area, with the shallowest groundwater levels occurring beneath the furthest downgradient recharge basins. At a recharge rate of 2.1 acre-ft/day, the maximum predicted recharge for this study was approximately 380 acre-ft/yr, based on a six-month recharge period.

Recharge Water Subsurface Travel Time to the Nearest Downgradient Well

The particle tracking analysis shows that the recharge water will reach the nearest production well (Sheephorn Well) in a little more than approximately 13 months (see Figure 4). Assuming the Sand Canyon recharge project would fall under the definition of a Groundwater Replenishment Reuse Project (GRRP), per DDW regulations, the required subsurface retention time for the recharge water is 2 months. For preliminary recharge siting purposes, a "credit" of 0.25 is applied for travel time calculations using an analytical model, as was done for this analysis. Thus, the credited retention time is interpreted to be 9.75 months (39 x 0.25). This credited retention time is less than the retention time simulated for this analysis (13 months), indicating that the sites simulated are feasible based on the data assumptions in the analysis.

The limiting factors for recharge capacity, as identified by this analysis, were infiltration rate and groundwater mounding in proximity to the land surface. Further data collection will be necessary to determine the total recharge potential of the Sand Canyon area of interest. The most

[2] Geoscience, 1990. Geohydrologic Characteristics and Artificial Recharge Potential of the Sand Canyon Area.

representative infiltration rates can be obtained through a pilot infiltration test. The test would consist of a controlled release of water into a portion of the channel where the water can be dammed up and temporarily ponded. The water level stage in the ponded area can be measured using a staff gage. Once the depth of the ponded area was sufficient (1 to 2 ft deep), the discharge into the channel would be discontinued and the rate of infiltration measured using the staff gage. Optimally, a succession of multiple wetting and drying cycles would be conducted to obtain an average infiltration rate. If possible, the test should also be conducted at multiple locations along the channel, to determine differences in infiltration rate with location.

Native Subsurface Underflow to the Recharge Area

As the aquifer beneath the Sand Canyon area is conceptualized as being unconfined, native subsurface underflow contribution to the portion of the aquifer beneath the recharge area was estimated based on the Dupuit Equation[3], which is expressed as:

$$Q = 0.5K\left(\frac{(h_1 - h_2)^2}{L}\right)$$

Where:

Q	=	Subsurface flow, (acre-ft)
K	=	Hydraulic Conductivity, (ft/day)
h_1	=	Initial Hydraulic head, (ft amsl)
h_2	=	Ending Hydraulic head, (ft amsl)
L	=	Flow Length (ft)

The change in hydraulic head was determined based on the contour map published in Geoscience (1990). The hydraulic conductivity was assumed to be 1 ft/day based on a pumping test conducted in the Sheephorn Well. A summary of the underflow analysis is provided in Table 1. The volume of underflow that may be applied toward the diluent requirement will likely depend on DDW review and interpretation of the data. A range of potential diluent credit was developed such that the low end of the range represents the underflow directly beneath the Sand Canyon channel and the high end of the range represents the entire flow net that ultimately contributes

[3] Fetter, 1994. Applied Hydrogeology, 3rd Edition. MacMillan College Publishing Co.

underflow to the Sand Canyon area, as shown on Figure 1. The range is approximately 58 acre-ft/yr to 247 acre-ft/yr (see Table 1).

Subject: Report of Waste Discharge for Big Bear Area Regional Wastewater Agency Regional Treatment Plant (Replenish Big Bear)

Dear Ms. Joy,

On behalf of Replenish Big Bear project team, please find attached the Report of Waste Discharge (ROWD) for Big Bear Area Regional Wastewater Agency (BBARWA) Regional Treatment Plant. This ROWD is to request a National Pollutant Discharge Elimination System (NPDES) permit for two new discharges locations at 1) to Stanfield Marsh Wildlife and Waterfowl Preserve (Stanfield Marsh), a tributary of Big Bear Lake (Lake) and 2) a separate discharge to Shay Pond, a tributary of Shay Creek.

BBARWA has partnered with Big Bear City Community Service District (BBCCSD), Big Bear Lake Department of Water and Power (BBLDWP), Big Bear Municipal Water District (BBMWD), and Bear Valley Basin Groundwater Sustainability Agency (BVBGSA), collectively known as the Agency Team, to develop the Replenish Big Bear Program. The Replenish Big Bear Program is intended to help protect the Big Bear Valley (Valley) and the Santa Ana Watershed from the impacts of drought and variable precipitation by recovering a water resource currently discharged outside of the watershed. The program is comprised of several elements; the first project includes treatment upgrades at the BBARWA regional wastewater treatment plant (WWTP) to produce disinfected, advanced treated effluent by providing tertiary filtration, reverse osmosis (RO) treatment, and ultraviolet (UV) disinfection for 100% of the water proposed to be discharged at the two new locations.

The proposed project and subject of this ROWD is the discharge of disinfected, advanced treated BBARWA effluent to (1) Stanfield Marsh/Big Bear Lake at a discharge rate up to 2,210 AFY and (2) Shay Pond at a discharge rate up to 80 AFY, is determined to comprise best practicable treatment and control and is consistent with federal and state antidegradation policies. The information supporting this finding is provided in the ROWD submittal package, which consists of the following:

I. ROWD Forms

- California EPA Form 200
- NPDES Form 2A
- NPDES Form 2S
- Location Maps
- Treatment Process Description

II. Supplemental Information
- Attachment A. Secondary Effluent and Receiving Water Characterization Data
- Attachment B. Technical Memo: Approach to Address Big Bear Lake Nutrient Total Maximum Daily Load in the NPDES Permit for Big Bear Area Regional Wastewater Agency
- Attachment C. Antidegradation Analysis for Proposed Discharges to Stanfield Marsh/Big Bear Lake and Shay Pond

Note that BBARWA previously held an NPDES permit for discharge to Stanfield Marsh (Order No. 00-12 NPDES No. CA8000344), which was replaced with Waste Discharge Requirements (WDRs) in 2005 because the discharge point was not being used. This expired NPDES number is included in the ROWD forms for reference.

We look forward to further engaging with you and your team on this project and are committed to working cooperatively to implement *Replenish Big Bear* to benefit the Big Bear Valley as well as the greater Santa Ana River Watershed.

Following your review of this ROWD submittal, we would like to request a meeting with key members of your team to discuss any feedback or requests for additional information so that the project team can respond as quickly as possible to keep this critical project moving forward.

We look forward to your review and feedback for next steps. If you have any questions in the meantime, please call or email me at the contact information listed below.

Sincerely,

David Lawrence, PE

II. TYPE OF DISCHARGE

Check Type of Discharge(s) Described in this Application:

☐ **Waste Discharge to Land** ☑ **Waste Discharge to Surface Water**

Check all that apply:

☐ Animal or Aquacultural Wastewater
☐ Animal Waste Solids
☑ Biosolids/Residual
☐ Cooling Water
☑ Domestic/ Municipal Wastewater Treatment and Disposal
☐ Dredge Material Disposal
☐ Hazardous Waste (*see instructions*)
☐ Industrial Process Wastewater
☐ Land Treatment Unit
☐ Landfill (*see instructions*)
☐ Mining
☐ Storm Water
☐ Surface Impoundment
☐ Waste Pile
☐ Wastewater Reclamation
☐ Other, *please describe* _____

III. LOCATION OF THE FACILITY

Describe the physical location of the facility:

1. Assessor's Parcel Number(s)
   Facility: 0449-082-040000
   Discharge Point: N/A
2. Latitude
   Facility: 34° 16' 4.2" N
   Discharge Point: 34° 15' 46.5" N (Stanfield Marsh), 34° 15' 14.7"N (Shay Pond)
3. Longitude
   Facility: 116° 48' 55.6" W
   Discharge Point: 116° 51' 58.9" W (Stanfield Marsh), 116° 48' 30.2"W (Shay Pond)

IV. REASON FOR FILING

Check all that apply:

- ☑ New Discharge or Facility
- ☑ Change in Design or Operation
- ☐ Change in Quantity/Type of Discharge
- ☐ Changes in Ownership/Operator (see instructions)
- ☑ Waste Discharge Requirements Update or NPDES Permit Reissuance
- ☐ Other: _____

V. CALIFORNIA ENVIRONMENTAL QUALITY ACT (CEQA)

Name of Lead Agency Big Bear Area Regional Wastewater Agency

Has a public agency determined that the proposed project is exempt from CEQA?

☐ Yes ☑ No

If yes, state the basis for the exemption and the name of the agency supplying the exemption on the line below:

_____

_____

Has a "Notice of Determination" been filed under CEQA?

☐ Yes ☑ No

If Yes, enclose a copy of the CEQA document, Environmental Impact Report (EIR), or Negative Declaration. If No, identify the expected type of CEQA document and expected date of completion.

Expected CEQA Documents: ☑ EIR ☐ Negative Declaration

Expected CEQA Completion Date: June 2023

VI. OTHER REQUIRED INFORMATION

Please provide a COMPLETE characterization of your discharge. A complete characterization includes, but is not limited to, design and actual flows, a list of constituents and the discharge concentration of each constituent, a list of other appropriate waste discharge characteristics, a description and schematic drawing of all treatment processes, a description of any Best Management Practices (BMPs) used, and a description of disposal methods.

Also include a site map showing the location of the facility and, if you are submitting this application for an NPDES permit, identify the surface water to which you propose to discharge. Please try to limit your maps to a scale of 1:24,000 (7.5' USGS Quadrangle) or a street map, if more appropriate.

VII. OTHER

Attach additional sheets to explain any responses which need clarification. List attachments with titles and dates below:

NPDES Forms 2A and 2S, facility maps (January 2022), treatment process narrative and schematics.

You will be notified by a representative of the RWQCB within 30 days of receipt of your application. The notice will state if your application is complete or if there is additional information you must submit to complete your Application/Report of Waste Discharge, pursuant to Division 7, Section 13260 of the California Water Code.

VIII. CERTIFICATION

"I certify under penalty of law that this document, including all attachments and supplemental information, were prepared under my direction and supervision in accordance with a system designed to assure that qualified personnel properly gathered and evaluated the information submitted. Based on my inquiry of the person or persons who manage the system, or those persons directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fine and imprisonment."

Treated Effluent	**Untreated Effluent**	**Combined Sewer Overflows**	**Bypasses**	**Constructed Emergency Overflows**
2 proposed				

Outfalls and Other Discharge or Disposal Methods

Outfalls Other Than to Waters of the United States

1.12 Does the POTW discharge wastewater to basins, ponds, or other surface impoundments that do not have outlets for discharge to waters of the United States?

☑ Yes ☐ No ➔ SKIP to Item 1.14.

1.13 Provide the location of each surface impoundment and associated discharge information in the table below.

Surface Impoundment Location and Discharge Data

Location	Average Daily Volume Discharged to Surface Impoundment	Continuous or Intermittent (check one)
Lucerne Valley reservoir (Colorado River Basin RWB)	2,120,000 gpd	☑ Continuous ☐ Intermittent See Note below
	gpd	☐ Continuous ☐ Intermittent
	gpd	☐ Continuous ☐ Intermittent

1.14 Is wastewater applied to land?

☑ Yes ☐ No ➔ SKIP to Item 1.16.

1.15 Provide the land application site and discharge data requested below.

Land Application Site and Discharge Data

Location	Size	Average Daily Volume Applied	Continuous or Intermittent (check one)
Lucerne Valley, CA-247 and Camp Rock Rd	340 acres	See Note below 2,120,000 gpd	☑ Continuous ☐ Intermittent
	acres	gpd	☐ Continuous ☐ Intermittent
	acres	gpd	☐ Continuous ☐ Intermittent

1.16 Is effluent transported to another facility for treatment prior to discharge?

☐ Yes ☑ No ➔ SKIP to Item 1.21.

1.17 Describe the means by which the effluent is transported (e.g., tank truck, pipe).

1.18 Is the effluent transported by a party other than the applicant?

☐ Yes ☐ No ➔ SKIP to Item 1.20.

1.19 Provide information on the transporter below.

Transporter Data

Entity name	Mailing address (street or P.O. box)	
City or town	State	ZIP code
Contact name (first and last)	Title	
Phone number	Email address	

Note: After treatment upgrades, up to 2.2 MGD of treated effluent will be sent to outfalls and only any additional flow will be sent to the Lucerne Valley reservoir surface impoundment or land application (permitted under the WDRs).

Outfalls and Other Discharge or Disposal Methods Continued

1.20 In the table below, indicate the name, address, contact information, NPDES number, and average daily flow rate of the receiving facility.

Receiving Facility Data

Facility name	Mailing address (street or P.O. box)	
City or town	State	ZIP code
Contact name (first and last)	Title	
Phone number	Email address	
NPDES number of receiving facility (if any) ☐ None	Average daily flow rate mgd	

1.21 Is the wastewater disposed of in a manner other than those already mentioned in Items 1.14 through 1.21 that do not have outlets to waters of the United States (e.g., underground percolation, underground injection)?

☐ Yes ☑ No ➔ SKIP to Item 1.23.

1.22 Provide information in the table below on these other disposal methods.

Information on Other Disposal Methods

Disposal Method Description	Location of Disposal Site	Size of Disposal Site	Annual Average Daily Discharge Volume	Continuous or Intermittent (check one)
		acres	gpd	☐ Continuous ☐ Intermittent
		acres	gpd	☐ Continuous ☐ Intermittent
		acres	gpd	☐ Continuous ☐ Intermittent

Variance Requests

1.23 Do you intend to request or renew one or more of the variances authorized at 40 CFR 122.21(n)? (Check all that apply. Consult with your NPDES permitting authority to determine what information needs to be submitted and when.)

☐ Discharges into marine waters (CWA Section 301(h))

☐ Water quality related effluent limitation (CWA Section 302(b)(2))

☑ Not applicable

Contractor Information

1.24 Are any operational or maintenance aspects (related to wastewater treatment and effluent quality) of the treatment works the responsibility of a contractor?

☐ Yes ☑ No ➔SKIP to Section 2.

1.25 Provide location and contact information for each contractor in addition to a description of the contractor's operational and maintenance responsibilities.

Contractor Information

	Contractor 1	Contractor 2	Contractor 3
Contractor name (company name)			
Mailing address (street or P.O. box)			
City, state, and ZIP code			
Contact name (first and last)			
Phone number			
Email address			
Operational and maintenance responsibilities of contractor			

SECTION 2. ADDITIONAL INFORMATION (40 CFR 122.21(j)(1) and (2))

Design Flow

Outfalls to Waters of the United States

2.1 Does the treatment works have a design flow greater than or equal to 0.1 mgd?

☑ Yes ☐ No ➔ SKIP to Section 3.

Inflow and Infiltration

2.2 Provide the treatment works' current average daily volume of inflow and infiltration.

Average Daily Volume of Inflow and Infiltration	
(Difference between wet and dry season influent flow between 2016-2021).	598,000 gpd

Indicate the steps the facility is taking to minimize inflow and infiltration.

Only the 18" and 20" trunk lines and force main pump station are the responsibility of the applicant. Video inspection is performed every four years. The most recent inspection identified seven areas that will require maintenance within 5-10 years.

Topographic Map

2.3 Have you attached a topographic map to this application that contains all the required information? (See instructions for specific requirements.)

☑ Yes ☐ No

Flow Diagram

2.4 Have you attached a process flow diagram or schematic to this application that contains all the required information? (See instructions for specific requirements.)

☑ Yes ☐ No

Scheduled Improvements and Schedules of Implementation

2.5 Are improvements to the facility scheduled?

☑ Yes ☐ No ➔ SKIP to Section 3.

Briefly list and describe the scheduled improvements.

1. See the Treatment Process Narrative (Section V).
2.
3.
4.

2.6 Provide scheduled or actual dates of completion for improvements.

Scheduled or Actual Dates of Completion for Improvements

Scheduled Improvement (from above)	Affected Outfalls (list outfall number)	Begin Construction (MM/DD/YYYY)	End Construction (MM/DD/YYYY)	Begin Discharge (MM/DD/YYYY)	Attainment of Operational Level (MM/DD/YYYY)
1.	001, 002		06/30/2026	07/01/2026	
2.					
3.					
4.					

2.7 Have appropriate permits/clearances concerning other federal/state requirements been obtained? Briefly explain your response.

☐ Yes ☑ No ☐ None required or applicable

Explanation:

All required federal permits will be obtained before construction begins.

SECTION 3. INFORMATION ON EFFLUENT DISCHARGES (40 CFR 122.21(j)(3) to (5))

Description of Outfalls

3.1 Provide the following information for each outfall. (Attach additional sheets if you have more than three outfalls.)

	Outfall Number 001	Outfall Number 002	Outfall Number _____
State	CA	CA	
County	San Bernardino	San Bernardino	
City or town	Big Bear City	Big Bear City	
Distance from shore	N/A ft.	N/A ft.	ft.
Depth below surface	N/A ft.	N/A ft.	ft.
Average daily flow rate	2.2 mgd	0.0714 mgd	mgd
Latitude	34° 15′ 46.5″ N	34° 15′ 14.7″ N	° ′ ″
Longitude	116° 51′ 58.9″ W	116° 48′ 30.2″ W	° ′ ″

Seasonal or Periodic Discharge Data

3.2 Do any of the outfalls described under Item 3.1 have seasonal or periodic discharges?

☐ Yes ☑ No ➔ SKIP to Item 3.4.

3.3 If so, provide the following information for each applicable outfall.

	Outfall Number _____	Outfall Number _____	Outfall Number _____
Number of times per year discharge occurs			
Average duration of each discharge (specify units)			
Average flow of each discharge	mgd	mgd	mgd
Months in which discharge occurs			

Diffuser Type

3.4 Are any of the outfalls listed under Item 3.1 equipped with a diffuser?

☐ Yes ☑ No ➔ SKIP to Item 3.6.

3.5 Briefly describe the diffuser type at each applicable outfall.

	Outfall Number _____	Outfall Number _____	Outfall Number _____

Waters of the U.S.

3.6 Does the treatment works discharge or plan to discharge wastewater to waters of the United States from one or more discharge points?

☑ Yes ☐ No ➔SKIP to Section 6.

Receiving Water Description

3.7 Provide the receiving water and related information (if known) for each outfall.

	Outfall Number 001	Outfall Number 002	Outfall Number _____
Receiving water name	Stanfield Marsh	Shay Pond [See Note below]	
Name of watershed, river, or stream system	Big Bear Lake	Shay Creek	
U.S. Soil Conservation Service 14-digit watershed code	341429116583101	N/A	
Name of state management/river basin	N/A	N/A	
U.S. Geological Survey 8-digit hydrologic cataloging unit code	N/A	N/A	
Critical low flow (acute)	N/A cfs	N/A cfs	cfs
Critical low flow (chronic)	N/A cfs	N/A cfs	cfs
Total hardness at critical low flow	157 mg/L of $CaCO_3$	180 (1 value) mg/L of $CaCO_3$	mg/L of $CaCO_3$

Treatment Description

3.8 Provide the following information describing the treatment provided for discharges from each outfall.

	Outfall Number 001	Outfall Number 002	Outfall Number _____
Highest Level of Treatment (check all that apply per outfall)	☑ Primary ☐ Equivalent to secondary ☑ Secondary ☑ Advanced ☑ Other (specify) Tertiary, NDN, RO	☑ Primary ☐ Equivalent to secondary ☑ Secondary ☑ Advanced ☑ Other (specify) Tertiary, NDN, RO	☐ Primary ☐ Equivalent to secondary ☐ Secondary ☐ Advanced ☐ Other (specify) _____
Design Removal Rates by Outfall	Anticipated values for the proposed treatment level:		
BOD_5 or $CBOD_5$	99 %	99 %	%
TSS	99 %	99 %	%
Phosphorus	☐ Not applicable 99 %	☐ Not applicable 99 %	☐ Not applicable %
Nitrogen	☐ Not applicable 98 %	☐ Not applicable 98 %	☐ Not applicable %
Other (specify) Total dissolved solids	☐ Not applicable 88 %	☐ Not applicable 88 %	☐ Not applicable %

Note: The status of Shay Pond as a water of the U.S. has yet to be determined.

Treatment Description Continued

3.9 Describe the type of disinfection used for the effluent from each outfall in the table below. If disinfection varies by season, describe below.

	Outfall Number 001	Outfall Number 002	Outfall Number _____
Disinfection type	Ultraviolet light	Ultraviolet light	
Seasons used	All	All	
Dechlorination used?	☑ Not applicable ☐ Yes ☐ No	☑ Not applicable ☐ Yes ☐ No	☐ Not applicable ☐ Yes ☐ No

Effluent Testing Data

3.10 Have you completed monitoring for all Table A parameters and attached the results to the application package?
☑ Yes [Secondary effluent monitoring] ☐ No

3.11 Have you conducted any WET tests during the 4.5 years prior to the date of the application on any of the facility's discharges or on any receiving water near the discharge points?
☐ Yes ☑ No ➔ SKIP to Item 3.13.

3.12 Indicate the number of acute and chronic WET tests conducted since the last permit reissuance of the facility's discharges by outfall number or of the receiving water near the discharge points.

	Outfall Number _____		Outfall Number _____		Outfall Number _____	
	Acute	Chronic	Acute	Chronic	Acute	Chronic
Number of tests of discharge water						
Number of tests of receiving water						

3.13 Does the treatment works have a design flow greater than or equal to 0.1 mgd?
☑ Yes ☐ No ➔ SKIP to Item 3.16.

3.14 Does the POTW use chlorine for disinfection, use chlorine elsewhere in the treatment process, or otherwise have reasonable potential to discharge chlorine in its effluent?
☐ Yes ➔ Complete Table B, including chlorine. ☑ No ➔ Complete Table B, omitting chlorine.

3.15 Have you completed monitoring for all applicable Table B pollutants and attached the results to this application package?
☑ Yes [Secondary effluent monitoring] ☐ No

3.16 Does one or more of the following conditions apply?
- The facility has a design flow greater than or equal to 1 mgd.
- The POTW has an approved pretreatment program or is required to develop such a program.
- The NPDES permitting authority has informed the POTW that it must sample for the parameters in Table C, must sample other additional parameters (Table D), or submit the results of WET tests for acute or chronic toxicity for each of its discharge outfalls (Table E).

☑ Yes ➔ Complete Tables C, D, and E as applicable. ☐ No ➔ SKIP to Section 4.

3.17 Have you completed monitoring for all applicable Table C pollutants and attached the results to this application package?
☑ Yes ☐ No

3.18 Have you completed monitoring for all applicable Table D pollutants required by your NPDES permitting authority and attached the results to this application package?
☑ Yes ☐ No additional sampling required by NPDES permitting authority.

Effluent Testing Data Continued

3.19	Has the POTW conducted either (1) minimum of four quarterly WET tests for one year preceding this permit application or (2) at least four annual WET tests in the past 4.5 years? ☐ Yes ☑ No ➔ Complete tests and Table E and SKIP to Item 3.26.
3.20	Have you previously submitted the results of the above tests to your NPDES permitting authority? ☐ Yes ☑ No ➔ Provide results in Table E and SKIP to Item 3.26.
3.21	Indicate the dates the data were submitted to your NPDES permitting authority and provide a summary of the results.

Date(s) Submitted (MM/DD/YYYY)	Summary of Results
	The existing secondary treatment process would not provide valid results. The required four quarterly WET tests will be performed once the treatment plant upgrades are complete.

3.22	Regardless of how you provided your WET testing data to the NPDES permitting authority, did any of the tests result in toxicity? ☐ Yes ☐ No ➔ SKIP to Item 3.26.
3.23	Describe the cause(s) of the toxicity:
3.24	Has the treatment works conducted a toxicity reduction evaluation? ☐ Yes ☐ No ➔ SKIP to Item 3.26.
3.25	Provide details of any toxicity reduction evaluations conducted.
3.26	Have you completed Table E for all applicable outfalls and attached the results to the application package? ☐ Yes [See note below] ☑ Not applicable because previously submitted information to the NPDES permitting authority.

SECTION 4. INDUSTRIAL DISCHARGES AND HAZARDOUS WASTES (40 CFR 122.21(j)(6) and (7))

Industrial Discharges and Hazardous Wastes

4.1	Does the POTW receive discharges from SIUs or NSCIUs? ☐ Yes ☑ No ➔ SKIP to Item 4.7.
4.2	Indicate the number of SIUs and NSCIUs that discharge to the POTW.

Number of SIUs	Number of NSCIUs

4.3	Does the POTW have an approved pretreatment program? ☐ Yes ☐ No
4.4	Have you submitted either of the following to the NPDES permitting authority that contains information substantially identical to that required in Table F: (1) a pretreatment program annual report submitted within one year of the application or (2) a pretreatment program? ☐ Yes ☐ No ➔ SKIP to Item 4.6.
4.5	Identify the title and date of the annual report or pretreatment program referenced in Item 4.4. SKIP to Item 4.7.
4.6	Have you completed and attached Table F to this application package? ☐ Yes ☐ No

Note: The treatment process will be upgraded prior to commencement of discharge. Toxicity testing will be performed at that time.

Industrial Discharges and Hazardous Wastes Continued

4.7 Does the POTW receive, or has it been notified that it will receive, by truck, rail, or dedicated pipe, any wastes that are regulated as RCRA hazardous wastes pursuant to 40 CFR 261?

☐ Yes ☑ No ➔ SKIP to Item 4.9.

4.8 If yes, provide the following information:

Hazardous Waste Number	Waste Transport Method (check all that apply)	Annual Amount of Waste Received	Units
	☐ Truck ☐ Rail ☐ Dedicated pipe ☐ Other (specify) _____		
	☐ Truck ☐ Rail ☐ Dedicated pipe ☐ Other (specify) _____		
	☐ Truck ☐ Rail ☐ Dedicated pipe ☐ Other (specify) _____		

4.9 Does the POTW receive, or has it been notified that it will receive, wastewaters that originate from remedial activities, including those undertaken pursuant to CERCLA and Sections 3004(7) or 3008(h) of RCRA?

☐ Yes ☑ No ➔ SKIP to Section 5.

4.10 Does the POTW receive (or expect to receive) less than 15 kilograms per month of non-acute hazardous wastes as specified in 40 CFR 261.30(d) and 261.33(e)?

☐ Yes ➔ SKIP to Section 5. ☐ No

4.11 Have you reported the following information in an attachment to this application: identification and description of the site(s) or facility(ies) at which the wastewater originates; the identities of the wastewater's hazardous constituents; and the extent of treatment, if any, the wastewater receives or will receive before entering the POTW?

☐ Yes ☐ No

SECTION 5. COMBINED SEWER OVERFLOWS (40 CFR 122.21(j)(8))

CSO Map and Diagram

5.1 Does the treatment works have a combined sewer system?

☐ Yes ☑ No ➔SKIP to Section 6.

5.2 Have you attached a CSO system map to this application? (See instructions for map requirements.)

☐ Yes ☐ No

5.3 Have you attached a CSO system diagram to this application? (See instructions for diagram requirements.)

☐ Yes ☐ No

CSO Outfall Description

5.4 For each CSO outfall, provide the following information. (Attach additional sheets as necessary.)

	CSO Outfall Number ____	CSO Outfall Number _____	CSO Outfall Number _____
City or town			
State and ZIP code			
County			
Latitude	° ' "	° ' "	° ' "
Longitude	° ' "	° ' "	° ' "
Distance from shore	ft.	ft.	ft.
Depth below surface	ft.	ft.	ft.

CSO Monitoring

5.5 Did the POTW monitor any of the following items in the past year for its CSO outfalls?

	CSO Outfall Number ____	CSO Outfall Number _____	CSO Outfall Number _____
Rainfall	☐ Yes ☐ No	☐ Yes ☐ No	☐ Yes ☐ No
CSO flow volume	☐ Yes ☐ No	☐ Yes ☐ No	☐ Yes ☐ No
CSO pollutant concentrations	☐ Yes ☐ No	☐ Yes ☐ No	☐ Yes ☐ No
Receiving water quality	☐ Yes ☐ No	☐ Yes ☐ No	☐ Yes ☐ No
CSO frequency	☐ Yes ☐ No	☐ Yes ☐ No	☐ Yes ☐ No
Number of storm events	☐ Yes ☐ No	☐ Yes ☐ No	☐ Yes ☐ No

CSO Events in Past Year

5.6 Provide the following information for each of your CSO outfalls.

	CSO Outfall Number ____	CSO Outfall Number ____	CSO Outfall Number ____
Number of CSO events in the past year	events	events	events
Average duration per event	hours ☐ Actual or ☐ Estimated	hours ☐ Actual or ☐ Estimated	hours ☐ Actual or ☐ Estimated
Average volume per event	million gallons ☐ Actual or ☐ Estimated	million gallons ☐ Actual or ☐ Estimated	million gallons ☐ Actual or ☐ Estimated
Minimum rainfall causing a CSO event in last year	inches of rainfall ☐ Actual or ☐ Estimated	inches of rainfall ☐ Actual or ☐ Estimated	inches of rainfall ☐ Actual or ☐ Estimated

CSO Receiving Waters

5.7 Provide the information in the table below for each of your CSO outfalls.

	CSO Outfall Number ___	CSO Outfall Number ___	CSO Outfall Number ___
Receiving water name			
Name of watershed/ stream system			
U.S. Soil Conservation Service 14-digit watershed code (if known)	☐ Unknown	☐ Unknown	☐ Unknown
Name of state management/river basin			
U.S. Geological Survey 8-Digit Hydrologic Unit Code (if known)	☐ Unknown	☐ Unknown	☐ Unknown
Description of known water quality impacts on receiving stream by CSO (see instructions for examples)			

SECTION 6. CHECKLIST AND CERTIFICATION STATEMENT (40 CFR 122.22(a) and (d))

Checklist and Certification Statement

6.1 In Column 1 below, mark the sections of Form 2A that you have completed and are submitting with your application. For each section, specify in Column 2 any attachments that you are enclosing to alert the permitting authority. Note that not all applicants are required to provide attachments.

Column 1	Column 2	
☑ Section 1: Basic Application Information for All Applicants	☐ w/ variance request(s)	☐ w/ additional attachments
☑ Section 2: Additional Information	☑ w/ topographic map ☑ w/ additional attachments	☑ w/ process flow diagram
☑ Section 3: Information on Effluent Discharges	☑ w/ Table A ☑ w/ Table B ☑ w/ Table C	☑ w/ Table D ☐ w/ Table E ☐ w/ additional attachments
☐ Section 4: Industrial Discharges and Hazardous Wastes	☐ w/ SIU and NSCIU attachments ☐ w/ additional attachments	☐ w/ Table F
☐ Section 5: Combined Sewer Overflows	☐ w/ CSO map ☐ w/ CSO system diagram	☐ w/ additional attachments
☑ Section 6: Checklist and Certification Statement	☐ w/ attachments	

6.2 **Certification Statement**

I certify under penalty of law that this document and all attachments were prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gather and evaluate the information submitted. Based on my inquiry of the person or persons who manage the system, or those persons directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fine and imprisonment for knowing violations.

Name (print or type first and last name)	Official title
David Lawrence	General Manager
Signature	Date signed 2/28/2022

EPA Identification Number	NPDES Permit Number	Facility Name	Outfall Number
	CA8000344	Big Bear City RTP	Current secondary

Form Approved 03/05/19
OMB No. 2040-0004

TABLE A. EFFLUENT PARAMETERS FOR ALL POTWS

Pollutant	Maximum Daily Discharge		Average Daily Discharge			Analytical Method[1]	ML or MDL (include units)
	Value	Units	Value	Units	Number of Samples		
Biochemical oxygen demand ☑ BOD_5 or ☐ $CBOD_5$ (report one)	36	mg/L	8.5	mg/L	301	SM 5210B	2 ☑ ML ☐ MDL
Fecal coliform	24,000	MPN/100mL	ND	MPN/100mL	2	SM 9221	1800 ☑ ML ☐ MDL
Flow rate	8.4	MGD	2.0	MGD	2131		
pH (minimum)	6.9	SU					
pH (maximum)	8.5	SU					
Temperature (winter)	16.0	C	12.2	C	181		
Temperature (summer)	21.5	C	18.1	C	184		
Total suspended solids (TSS)	44	mg/L	7.7	mg/L	298	SM 2540D	5 ☑ ML ☐ MDL

[1] Sampling shall be conducted according to sufficiently sensitive test procedures (i.e., methods) approved under 40 CFR 136 for the analysis of pollutants or pollutant parameters or required under 40 CFR chapter I, subchapter N or O. See instructions and 40 CFR 122.21(e)(3).

Note: Samples were collected from the currently existing facility which produces undisinfected secondary effluent, currently sent to land application under the WDRs. Future effluent discharged to surface water will be treated to tertiary levels followed by 100% reverse osmosis and UV disinfection after treatment plant upgrades.

1,2,4-Trichlorobenzene	ND	µg/L	ND	µg/L	1	EPA 624.1	0.79	5

Notes:

The secondary effluent dataset extends from June 2017 through November 2021.

Discharge to surface water will not commence until treatment plant upgrades are complete (estimated July 2026). Therefore, these data are not representative of future tertiary quality.

ND = All data were undetected below the MDL.

J = The result is estimated above the MDL and below the RL.

ID = There were insufficient detected data for calculating an average.

III. NPDES Form 2S - Biosolids

Part 2, Section 1 – General Information

Part 2, Section 2 – Generation of Sewage Sludge

Part 2, Section 3 – Land Application (not applicable)

Part 2, Section 4 – Surface Disposal (not applicable)

Part 2, Section 5 – Incineration (not applicable)

PART 2 **PERMIT APPLICATION INFORMATION (40 CFR 122.21(q))**

Complete this part if you have an effective NPDES permit or have been directed by the NPDES permitting authority to submit a full permit application. In other words, complete this part if your facility has, or is applying for, an NPDES permit.
Part 2 is divided into five sections. Section 1 pertains to all applicants. The applicability of Sections 2 to 5 depends on your facility's sewage sludge use or disposal practices. See the instructions to determine which sections you are required to complete.

PART 2, SECTION 1. GENERAL INFORMATION (40 CFR 122.21(q)(1 7) AND (q)(13))

General Information

All Part 2 applicants must complete this section.

Facility Information

1.1	Facility name Regional Treatment Plant, Big Bear City			
	Mailing address (street or P.O. box) 121 Palomino Drive, P.O. Box 517			
	City or town Big Bear City	State CA	ZIP code 92314	Phone number (909) 584-4520
	Contact name (first and last) John Shimmin	Title Plant Manager	Email address JShimmin@BBARWA.org	
	Location address (street, route number, or other specific identifier) 122 Palomino Drive		☐ Same as mailing address	
	City or town Big Bear City	State CA	ZIP code 92314	
1.2	Is this facility a Class I sludge management facility? ☐ Yes ☑ No			
1.3	**Facility Design Flow Rate**	4.89 million gallons per day (mgd)		
1.4	**Total Population Served**	19,354		
1.5	**Ownership Status** ☐ Public—federal ☐ Public—state ☑ Other public (specify) Municipal ☐ Private ☐ Other (specify) _____			

Applicant Information

1.6	Is applicant different from entity listed under Item 1.1 above? ☑ Yes ☐ No ➔SKIP to Item 1.8 (Part 2, Section 1).			
1.7	Applicant name Big Bear Area Regional Wastewater Agency			
	Applicant mailing address (street or P.O. box) 121 Palomino Drive, P.O. Box 517			
	City or town Big Bear City		State CA	ZIP code 92314
	Contact name (first and last) David Lawrence	Title General Manager	Phone number (909) 584-4521	Email address dlawrence@bbarwa.org
1.8	Is the applicant the facility's owner, operator, or both? (Check only one response.) ☐ Operator ☐ Owner ☑ Both			
1.9	To which entity should the NPDES permitting authority send correspondence? (Check only one response.) ☐ Facility ☑ Applicant ☐ Facility and applicant (they are one and the same)			

1.10	Facility's NPDES permit number ☐ Check here if you do not have an NPDES permit but are otherwise required to submit Part 2 of Form 2S.	See Note below CA8000344

1.11 Indicate all other federal, state, and local permits or construction approvals received or applied for that regulate this facility's sewage sludge management practices below.

☐ RCRA (hazardous wastes)	☐ Nonattainment program (CAA)	☐ NESHAPs (CAA)
☐ PSD (air emissions)	☐ Dredge or fill (CWA Section 404)	☐ Other (specify)
☐ Ocean dumping (MPRSA)	☐ UIC (underground injection of fluids)	

Indian Country

1.12 Does any generation, treatment, storage, application to land, or disposal of sewage sludge from this facility occur in Indian Country?

☐ Yes ☑ No ➔ SKIP to Item 1.14 (Part 2, Section 1) below.

1.13 Provide a description of the generation, treatment, storage, land application, or disposal of sewage sludge that occurs.

Topographic Map

1.14 Have you attached a topographic map containing all required information to this application? (See instructions for specific requirements.)

☑ Yes ☐ No

Line Drawing

1.15 Have you attached a line drawing and/or a narrative description that identifies all sewage sludge practices that will be employed during the term of the permit containing all the required information to this application? (See instructions for specific requirements.)

☑ Yes ☐ No

Contractor Information

1.16 Do contractors have any operational or maintenance responsibilities related to sewage sludge generation, treatment, use, or disposal at the facility?

☑ Yes ☐ No ➔ SKIP to Item 1.18 (Part 2, Section 1) below.

1.17 Provide the following information for each contractor.

☐ Check here if you have attached additional sheets to the application package.

	Contractor 1	Contractor 2	Contractor 3
Contractor company name	Ag Tech LLC	Synagro West, LLC	
Mailing address (street or P.O. box)	3895 W. County 19th St	14479 Cougar Road	
City, state, and ZIP code	Somerton, AZ 85350	Helendale, CA 92342	
Contact name (first and last)	Cal Mullenix	Jamie Little	
Telephone number	(602) 377-7250	(661) 765-2200	
Email address	cal@westexp.com	jlittle@synagro.com	

Note: This NPDES permit for discharge to surface water expired February 1, 2005.

General Information Continued

1.17 cont.		Contractor 1	Contractor 2	Contractor 3
	Responsibilities of contractor	Sludge hauling through August 2021.	Sludge hauling beginning September 2021.	

Pollutant Concentrations

Using the table below or a separate attachment, provide sewage sludge monitoring data for the pollutants for which limits in sewage sludge have been established in 40 CFR 503 for this facility's expected use or disposal practices. All data must be based on three or more samples taken at least one month apart and must be no more than 4.5 years old.

[Based on 15 samples collected between 2018-2021.]

☐ Check here if you have attached additional sheets to the application package.

1.18

Pollutant	Average Monthly Concentration (mg/kg dry weight)	Analytical Method	Detection Level
Arsenic	ND	EPA 6010	10
Cadmium	ND	EPA 6010	5
Chromium	8.4	EPA 6010	14
Copper	239	EPA 6010	-
Lead	12.2	EPA 6010	17
Mercury	0.55	EPA 7471	0.66
Molybdenum	4.9	EPA 6010	8
Nickel	8.7	EPA 6010	8
Selenium	ND	EPA 6010	1-30
Zinc	524	EPA 6010	-

Checklist and Certification Statement

1.19 In Column 1 below, mark the sections of Form 2S, Part 2, that you have completed and are submitting with your application. For each section, specify in Column 2 any attachments that you are enclosing. Note that not all applicants are required to complete all sections or provide attachments. See Exhibit 2S–2 in the Instructions.

Column 1	Column 2
☑ Section 1 (General Information)	☐ w/ attachments
☑ Section 2 (Generation of Sewage Sludge or Preparation of a Material Derived from Sewage Sludge)	☑ w/ attachments
☐ Section 3 (Land Application of Bulk Sewage Sludge)	☐ w/ attachments
☐ Section 4 (Surface Disposal)	☐ w/ attachments
☐ Section 5 (Incineration)	☐ w/ attachments

1.20 **Certification Statement**

I certify under penalty of law that this document and all attachments were prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gather and evaluate the information submitted. Based on my inquiry of the person or persons who manage the system, or those persons directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fine and imprisonment for knowing violations.

Name (print or type first and last name)	Official title
David Lawrence	General Manager
Signature [signature]	Date signed 2/28/2022
Telephone number (909) 584-4521	

Upon the request of the NPDES permitting authority, you must submit any other information the authority deems necessary to assess sewage sludge use or disposal practices at your facility and identify appropriate permitting requirements.

PART 2, SECTION 2. GENERATION OF SEWAGE SLUDGE OR PREPARATION OF A MATERIAL DERIVED FROM SEWAGE SLUDGE (40 CFR 122.21(q)(8) THROUGH (12))

Generation of Sewage Sludge or Preparation of a Material Derived from Sewage Sludge

2.1 Does your facility generate sewage sludge or derive a material from sewage sludge?

☑ Yes ☐ No ➔ SKIP to Part 2, Section 3.

Amount Generated Onsite

2.2 Total dry metric tons per 365-day period generated at your facility: 610

Amount Received from Off Site Facility

2.3 Does your facility receive sewage sludge from another facility for treatment use or disposal?

☐ Yes ☑ No ➔SKIP to Item 2.8 (Part 2, Section 2) below.

2.4 Indicate the total number of facilities from which you receive sewage sludge for treatment, use, or disposal:

Provide the following information for each of the facilities from which you receive sewage sludge.

☐ Check here if you have attached additional sheets to the application package.

2.5

Name of facility			
Mailing address (street or P.O. box)			
City or town		State	ZIP code
Contact name (first and last)	Title	Phone number	Email address
Location address (street, route number, or other specific identifier)			☐ Same as mailing address
City or town		State	ZIP code
County		County code	☐ Not available

2.6 Indicate the amount of sewage sludge received, the applicable pathogen class and reduction alternative, and the applicable vector reduction option provided at the offsite facility.

Amount (dry metric tons)	Pathogen Class and Reduction Alternative	Vector Attraction Reduction Option
	☐ Not applicable ☐ Class A, Alternative 1 ☐ Class A, Alternative 2 ☐ Class A, Alternative 3 ☐ Class A, Alternative 4 ☐ Class A, Alternative 5 ☐ Class A, Alternative 6 ☐ Class B, Alternative 1 ☐ Class B, Alternative 2 ☐ Class B, Alternative 3 ☐ Class B, Alternative 4 ☐ Domestic septage, pH adjustment	☐ Not applicable ☐ Option 1 ☐ Option 2 ☐ Option 3 ☐ Option 4 ☐ Option 5 ☐ Option 6 ☐ Option 7 ☐ Option 8 ☐ Option 9 ☐ Option 10 ☐ Option 11

2.7 Identify the treatment process(es) that are known to occur at the offsite facility, including blending activities and treatment to reduce pathogens or vector attraction properties. (Check all that apply.)

☐ Preliminary operations (e.g., sludge grinding and degritting)
☐ Thickening (concentration)
☐ Stabilization
☐ Anaerobic digestion
☐ Composting
☐ Conditioning
☐ Disinfection (e.g., beta ray irradiation, gamma ray irradiation, pasteurization)
☐ Dewatering (e.g., centrifugation, sludge drying beds, sludge lagoons)
☐ Heat drying
☐ Thermal reduction
☐ Methane or biogas capture and recovery
☐ Other (specify) _____

Generation of Sewage Sludge or Preparation of a Material Derived from Sewage Sludge Continued

Treatment Provided at Your Facility

2.8 For each sewage sludge use or disposal practice, indicate the applicable pathogen class and reduction alternative and the applicable vector attraction reduction option provided at your facility. Attach additional pages, as necessary.

Use or Disposal Practice (check one)	Pathogen Class and Reduction Alternative	Vector Attraction Reduction Option
☐ Land application of bulk sewage	☐ Not applicable	☐ Not applicable
☐ Land application of biosolids (bulk)	☐ Class A, Alternative 1	☐ Option 1
☐ Land application of biosolids (bags)	☐ Class A, Alternative 2	☐ Option 2
☐ Surface disposal in a landfill	☐ Class A, Alternative 3	☐ Option 3
☑ Other surface disposal	☐ Class A, Alternative 4	☐ Option 4
☐ Incineration	☐ Class A, Alternative 5	☐ Option 5
	☐ Class A, Alternative 6	☐ Option 6
	☐ Class B, Alternative 1	☐ Option 7
	☑ Class B, Alternative 2	☐ Option 8
	☐ Class B, Alternative 3	☐ Option 9
	☐ Class B, Alternative 4	☑ Option 10
	☐ Domestic septage, pH adjustment	☐ Option 11

2.9 Identify the treatment process(es) used at your facility to reduce pathogens in sewage sludge or reduce the vector attraction properties of sewage sludge? (Check all that apply.)

- ☑ Preliminary operations (e.g., sludge grinding and degritting)
- ☐ Thickening (concentration)
- ☐ Stabilization
- ☐ Anaerobic digestion
- ☐ Composting
- ☐ Conditioning
- ☐ Disinfection (e.g., beta ray irradiation, gamma ray irradiation, pasteurization)
- ☑ Dewatering (e.g., centrifugation, sludge drying beds, sludge lagoons)
- ☐ Heat drying
- ☐ Thermal reduction
- ☐ Methane or biogas capture and recovery

2.10 Describe any other sewage sludge treatment or blending activities not identified in Items 2.8 and 2.9 (Part 2, Section 2) above.

☐ Check here if you have attached the description to the application package.

Preparation of Sewage Sludge Meeting Ceiling and Pollutant Concentrations, Class A Pathogen Requirements, and One of Vector Attraction Reduction Options 1 to 8

2.11 Does the sewage sludge from your facility meet the ceiling concentrations in Table 1 of 40 CFR 503.13, the pollutant concentrations in Table 3 of 40 CFR 503.13, Class A pathogen reduction requirements at 40 CFR 503.32(a), *and* one of the vector attraction reduction requirements at 40 CFR 503.33(b)(1)–(8) and is it land applied?

☐ Yes ☑ No ➔ SKIP to Item 2.14 (Part 2, Section 2) below.

2.12 Total dry metric tons per 365-day period of sewage sludge subject to this subsection that is applied to the land:

2.13 Is sewage sludge subject to this subsection placed in bags or other containers for sale or give-away for application to the land?

☐ Yes ☐ No

☑ Check here once you have completed Items 2.11 to 2.13, then ➔ SKIP to Item 2.32 (Part 2, Section 2) below.

Generation of Sewage Sludge or Preparation of a Material Derived from Sewage Sludge Continued

Sale or Give-Away in a Bag or Other Container for Application to the Land

2.14 Do you place sewage sludge in a bag or other container for sale or give-away for land application?

☐ Yes ☑ No ➔ SKIP to Item 2.17 (Part 2, Section 2) below.

2.15 Total dry metric tons per 365-day period of sewage sludge placed in a bag or other container at your facility for sale or give-away for application to the land:

2.16 Attach a copy of all labels or notices that accompany the sewage sludge being sold or given away in a bag or other container for application to the land.

☐ Check here to indicate that you have attached all labels or notices to this application package.

☑ Check here once you have completed Items 2.14 to 2.16, then ➔ SKIP to Part 2, Section 2, Item 2.32.

Shipment Off Site for Treatment or Blending

2.17 Does another facility provide treatment or blending of your facility's sewage sludge? (This question does not pertain to dewatered sludge sent directly to a land application or surface disposal site.)

☑ Yes ☐ No ➔ SKIP to Item 2.32 (Part 2, Section 2) below.

2.18 Indicate the total number of facilities that provide treatment or blending of your facility's sewage sludge. Provide the information in Items 2.19 to 2.26 (Part 2, Section 2) below for each facility.

☑ Check here if you have attached additional sheets to the application package.

1 primary, 1 backup

2.19 Name of receiving facility
Nursery Products Hawes Composting Facility

Mailing address (street or P.O. box)
14479 Cougar Rd

City or town	State	ZIP code
Helendale	CA	92342

Contact name (first and last)	Title	Phone number	Email address
Venny Vasquez	Site Manager	(760) 265-5210	vvasquez@synagro.com

Location address (street, route number, or other specific identifier) ☑ Same as mailing address

City or town	State	ZIP code

2.20 Total dry metric tons per 365-day period of sewage sludge provided to receiving facility: 610

2.21 Does the receiving facility provide additional treatment to reduce pathogens in sewage sludge from your facility or reduce the vector attraction properties of sewage sludge from your facility?

☑ Yes ☐ No ➔ SKIP to Item 2.24 (Part 2, Section 2) below.

2.22 Indicate the pathogen class and reduction alternative and the vector attraction reduction option met for the sewage sludge at the receiving facility.

Pathogen Class and Reduction Alternative	Vector Attraction Reduction Option
☐ Not applicable	☐ Not applicable
☐ Class A, Alternative 1	☐ Option 1
☐ Class A, Alternative 2	☐ Option 2
☐ Class A, Alternative 3	☐ Option 3
☐ Class A, Alternative 4	☐ Option 4
☑ Class A, Alternative 5	☑ Option 5
☐ Class A, Alternative 6	☐ Option 6
☐ Class B, Alternative 1	☐ Option 7
☐ Class B, Alternative 2	☐ Option 8
☐ Class B, Alternative 3	☐ Option 9
☐ Class B, Alternative 4	☐ Option 10
☐ Domestic septage, pH adjustment	☐ Option 11

Generation of Sewage Sludge or Preparation of a Material Derived from Sewage Sludge Continued

2.23 Which treatment process(es) are used at the receiving facility to reduce pathogens in sewage sludge or reduce the vector attraction properties of sewage sludge from your facility? (Check all that apply.)

- ☐ Preliminary operations (e.g., sludge grinding and degritting)
- ☐ Thickening (concentration)
- ☐ Stabilization
- ☐ Anaerobic digestion
- ☑ Composting
- ☐ Conditioning
- ☐ Disinfection (e.g., beta ray irradiation, gamma ray irradiation, pasteurization)
- ☐ Dewatering (e.g., centrifugation, sludge drying beds, sludge lagoons)
- ☐ Heat drying
- ☐ Thermal reduction
- ☐ Methane or biogas capture and recovery
- ☐ Other (specify) _____

2.24 Attach a copy of any information you provide the receiving facility to comply with the "notice and necessary information" requirement of 40 CFR 503.12(g).

☐ Check here to indicate that you have attached material.

2.25 Does the receiving facility place sewage sludge from your facility in a bag or other container for sale or give-away for application to the land?

☐ Yes ☑ No ➔ SKIP to Item 2.32 (Part 2, Section 2) below.

2.26 Attach a copy of all labels or notices that accompany the product being sold or given away.

☐ Check here to indicate that you have attached material.

☑ Check here once you have completed Items 2.17 to 2.26 (Part 2, Section 2), then ➔ SKIP to Item 2.32 (Part 2, Section 2) below. [See additional pages for backup receiving facility.]

Land Application of Bulk Sewage Sludge

2.27 Is sewage sludge from your facility applied to the land?

☐ Yes ☑ No ➔ SKIP to Item 2.32 (Part 2, Section 2) below.

2.28 Total dry metric tons per 365-day period of sewage sludge applied to all land application sites: _____

2.29 Did you identify all land application sites in Part 2, Section 3 of this application?

☐ Yes ☐ No ➔ Submit a copy of the land application plan with your application.

2.30 Are any land application sites located in states other than the state where you generate sewage sludge or derive a material from sewage sludge?

☐ Yes ☐ No ➔ SKIP to Item 2.32 (Part 2, Section 2) below.

2.31 Describe how you notify the NPDES permitting authority for the states where the land application sites are located. Attach a copy of the notification.

☐ Check here if you have attached the explanation to the application package.

☐ Check here if you have attached the notification to the application package.

Surface Disposal

2.32 Is sewage sludge from your facility placed on a surface disposal site?

☐ Yes ☑ No ➔ SKIP to Item 2.39 (Part 2, Section 2) below.

2.33 Total dry metric tons of sewage sludge from your facility placed on all surface disposal sites per 365-day period: _____

2.34 Do you own or operate all surface disposal sites to which you send sewage sludge for disposal?

☐ Yes ➔ SKIP to Item 2.39 (Part 2, Section 2) below. ☐ No

2.35 Indicate the total number of surface disposal sites to which you send your sewage sludge. _____

(Provide the information in Items 2.36 to 2.38 of Part 2, Section 2, for each facility.)

☐ Check here if you have attached additional sheets to the application package.

Generation of Sewage Sludge or Preparation of a Material Derived from Sewage Sludge Continued

2.36	Site name or number of surface disposal site you do not own or operate			
	Mailing address (street or P.O. box)			
	City or Town		State	ZIP Code
	Contact Name (first and last)	Title	Phone Number	Email Address
2.37	Site Contact (Check all that apply.) ☐ Owner ☐ Operator			
2.38	Total dry metric tons of sewage sludge from your facility placed on this surface disposal site per 365-day period:			

Incineration

2.39	Is sewage sludge from your facility fired in a sewage sludge incinerator? ☐ Yes ☑ No ➔ SKIP to Item 2.46 (Part 2, Section 2) below.			
2.40	Total dry metric tons of sewage sludge from your facility fired in all sewage sludge incinerators per 365-day period:			
2.41	Do you own or operate all sewage sludge incinerators in which sewage sludge from your facility is fired? ☐ Yes ➔ SKIP to Item 2.46 (Part 2, Section 2) below. ☐ No			
2.42	Indicate the total number of sewage sludge incinerators used that you do not own or operate. (Provide the information in Items 2.43 to 2.45 directly below for each facility.) ☐ Check here if you have attached additional sheets to the application package.			
2.43	Incinerator name or number			
	Mailing address (street or P.O. box)			
	City or town		State	ZIP code
	Contact name (first and last)	Title	Phone number	Email address
	Location address (street, route number, or other specific identifier) ☐ Same as mailing address			
	City or town		State	ZIP code
2.44	Contact (check all that apply) ☐ Incinerator owner ☐ Incinerator operator			
2.45	Total dry metric tons of sewage sludge from your facility fired in this sewage sludge incinerator per 365-day period:			

Disposal in a Municipal Solid Waste Landfill

2.46	Is sewage sludge from your facility placed on a municipal solid waste landfill? ☐ Yes ☑ No ➔ SKIP to Part 2, Section 3.	
2.47	Indicate the total number of municipal solid waste landfills used. (Provide the information in Items 2.48 to 2.52 directly below for each facility.) ☐ Check here if you have attached additional sheets to the application package.	

Generation of Sewage Sludge or Preparation of a Material Derived from Sewage Sludge Continued

2.48	Name of landfill			
	Mailing address (street or P.O. box)			
	City or town		State	ZIP code
	Contact name (first and last)	Title	Phone number	Email address
	Location address (street, route number, or other specific identifier)			☐ Same as mailing address
	County	County code		☐ Not available
	City or town	State		ZIP code
2.49	Total dry metric tons of sewage sludge from your facility placed in this municipal solid waste landfill per 365-day period:			
2.50	List the numbers of all other federal, state, and local permits that regulate the operation of this municipal solid waste landfill.			

Permit Number	Type of Permit

2.51	Attach to the application information to determine whether the sewage sludge meets applicable requirements for disposal of sewage sludge in a municipal solid waste landfill (e.g., results of paint filter liquids test and TCLP test). ☐ Check here to indicate you have attached the requested information.
2.52	Does the municipal solid waste landfill comply with applicable criteria set forth in 40 CFR 258? ☐ Yes ☐ No

PART 2, SECTION 3 LAND APPLICATION OF BULK SEWAGE SLUDGE (40 CFR 122.21(q)(9))

Land Application of Bulk Sewage Sludge

3.1 Does your facility apply sewage sludge to land?

☐ Yes ☑ No ➔ SKIP to Part 2, Section 4.

3.2 Do any of the following conditions apply?

- The sewage sludge meets the ceiling concentrations in Table 1 of 40 CFR 503.12, the pollutant concentrations in Table 3 of 40 CFR 503.13, Class A pathogen reduction requirements at 40 CFR 503.32(a), *and* one of the vector attraction reduction requirements at 40 CFR 503.33(b)(1)–(8);
- The sewage sludge is sold or given away in a bag or other container for application to the land; or
- You provide the sewage sludge to another facility for treatment or blending.

☐ Yes ➔ SKIP to Part 2, Section 4. ☐ No

3.3 Complete Section 3 for every site on which the sewage sludge is applied.

☐ Check here if you have attached sheets to the application package for one or more land application sites.

Identification of Land Application Site

3.4 Site name or number

Location address (street, route number, or other specific identifier) ☐ Same as mailing address

County	County code ☐ Not available

City or town	State	ZIP code

Latitude/Longitude of Land Application Site (see instructions)

Latitude	Longitude
° ′ ″	° ′ ″

Method of Determination

☐ USGS map ☐ Field survey ☐ Other (specify) _____

3.5 Provide a topographic map (or other appropriate map if a topographic map is unavailable) that shows the site location.

☐ Check here to indicate you have attached a topographic map for this site.

Owner Information

3.6 Are you the owner of this land application site?

☐ Yes ➔ SKIP to Item 3.8 (Part 2, Section 3) below. ☐ No

3.7 Owner name

Mailing address (street or P.O. box)

City or town	State	ZIP code

Contact name (first and last)	Title	Phone number	Email address

Applier Information

3.8 Are you the person who applies, or who is responsible for application of, sewage sludge to this land application site?

☐ Yes ➔ SKIP to Item 3.10 (Part 2, Section 3) below. ☐ No

3.9 Applier's name

Mailing address (street or P.O. box)

City or town	State	ZIP code

Contact name (first and last)	Title	Phone number	Email address

Land Application of Bulk Sewage Sludge Continued

Site Type

3.10 Type of land application:

☐ Agricultural land ☐ Forest

☐ Reclamation site ☐ Public contact site

☐ Other (describe)

Crop or Other Vegetation Grown on Site

3.11 What type of crop or other vegetation is grown on this site?

3.12 What is the nitrogen requirement for this crop or vegetation?

Vector Attraction Reduction

3.13 Are the vector attraction reduction requirements at 40 CFR 503.33(b)(9) and (b)(10) met when sewage sludge is applied to the land application site?

☐ Yes ☐ No ➔ SKIP to Item 3.16 (Part 2, Section 3) below.

3.14 Indicate which vector attraction reduction option is met. (Check only one response.)

☐ Option 9 (injection below land surface) ☐ Option 10 (incorporation into soil within 6 hours)

3.15 Describe any treatment processes used at the land application site to reduce vector attraction properties of sewage sludge.

☐ Check here if you have attached your description to the application package.

Cumulative Loadings and Remaining Allotments

3.16 Is the sewage sludge applied to this site since July 20, 1993, subject to the cumulative pollutant loading rates (CPLRs) in 40 CFR 503.13(b)(2)?

☐ Yes ☐ No ➔ SKIP to Part 2, Section 4.

3.17 Have you contacted the NPDES permitting authority in the state where the bulk sewage sludge subject to CPLRs will be applied to ascertain whether bulk sewage sludge subject to CPLRs has been applied to this site on or since July 20, 1993?

☐ Yes ☐ No ➔ Sewage sludge subject to CPLRs may not be applied to this site. SKIP to Part 2, Section 4.

3.18 Provide the following information about your NPDES permitting authority:

NPDES permitting authority name	
Contact person	
Telephone number	
Email address	

3.19 Based on your inquiry, has bulk sewage sludge subject to CPLRs been applied to this site since July 20, 1993?

☐ Yes ☐ No ➔ SKIP to Part 2, Section 4.

3.20 Provide the following information for every facility other than yours that is sending, or has sent, bulk sewage sludge subject to CPLRs to this site since July 20, 1993. If more than one such facility sends sewage sludge to this site, attach additional pages as necessary.

☐ Check here to indicate that additional pages are attached.

Facility name			
Mailing address (street or P.O. box)			
City or town		State	ZIP code
Contact name (first and last)	Title	Phone number	Email address

PART 2, SECTION 4 SURFACE DISPOSAL (40 CFR 122.21(q)(10))

Surface Disposal

4.1 Do you own or operate a surface disposal site?

☐ Yes ☑ No ➔ SKIP to Part 2, Section 5.

4.2 Complete all items in Section 4 for each active sewage sludge unit that you own or operate.

☐ Check here to indicate that you have attached material to the application package for one or more active sewage sludge units.

Information on Active Sewage Sludge Units

4.3

Unit name or number			
Mailing address (street or P.O. box)			
City or town		State	ZIP code
Contact name (first and last)	Title	Phone number	Email address
Location address (street, route number, or other specific identifier)		☐ Same as mailing address	
County		County code ☐ Not available	
City or town		State	ZIP code

Latitude/Longitude of Active Sewage Sludge Unit (see instructions)

Latitude	Longitude
° ′ ″	° ′ ″

Method of Determination

☐ USGS map ☐ Field survey ☐ Other (specify) _____

4.4 Provide a topographic map (or other appropriate map if a topographic map is unavailable) that shows the site location.

☐ Check here to indicate that you have completed and attached a topographic map.

4.5	Total dry metric tons of sewage sludge placed on the active sewage sludge unit per 365-day period:	
4.6	Total dry metric tons of sewage sludge placed on the active sewage sludge unit over the life of the unit:	

4.7 Does the active sewage sludge unit have a liner with a maximum permeability of 1×10^{-7} centimeters per second (cm/sec)?

☐ Yes ☐ No ➔ SKIP to Item 4.9 (Part 2, Section 4) below.

4.8 Describe the liner.

☐ Check here to indicate that you have attached a description to the application package.

4.9 Does the active sewage sludge unit have a leachate collection system?

☐ Yes ☐ No ➔ SKIP to Item 4.11 (Part 2, Section 4) below.

4.10 Describe the leachate collection system and the method used for leachate disposal and provide the numbers of any federal, state, or local permit(s) for leachate disposal.

☐ Check here to indicate that you have attached the description to the application package.

Surface Disposal Continued

4.11	Is the boundary of the active sewage sludge unit less than 150 meters from the property line of the surface disposal site? ☐ Yes ☐ No ➔ SKIP to Item 4.13 (Part 2, Section 4) below.	
4.12	Provide the actual distance in meters:	meters
4.13	Remaining capacity of active sewage sludge unit in dry metric tons:	dry metric tons
4.14	Anticipated closure date for active sewage sludge unit, if known (MM/DD/YYYY):	
4.15	Attach a copy of any closure plan that has been developed for this active sewage sludge unit. ☐ Check here to indicate that you have attached a copy of the closure plan to the application package.	

Sewage Sludge from Other Facilities

4.16	Is sewage sludge sent to this active sewage sludge unit from any facilities other than your facility? ☐ Yes ☐ No ➔ SKIP to Item 4.21 (Part 2, Section 4) below.	
4.17	Indicate the total number of facilities (other than your facility) that send sewage sludge to this active sewage sludge unit. (Complete Items 4.18 to 4.20 directly below for each such facility.) ☐ Check here to indicate that you have attached responses for each facility to the application package.	

4.18 Facility name

Mailing address (street or P.O. box)

City or town		State	ZIP code
Contact name (first and last)	Title	Phone number	Email address

4.19 Indicate the pathogen class and reduction alternative and the vector attraction reduction option met for the sewage sludge before leaving the other facility.

Pathogen Class and Reduction Alternative	Vector Attraction Reduction Option
☐ Not applicable	☐ Not applicable
☐ Class A, Alternative 1	☐ Option 1
☐ Class A, Alternative 2	☐ Option 2
☐ Class A, Alternative 3	☐ Option 3
☐ Class A, Alternative 4	☐ Option 4
☐ Class A, Alternative 5	☐ Option 5
☐ Class A, Alternative 6	☐ Option 6
☐ Class B, Alternative 1	☐ Option 7
☐ Class B, Alternative 2	☐ Option 8
☐ Class B, Alternative 3	☐ Option 9
☐ Class B, Alternative 4	☐ Option 10
☐ Domestic septage, pH adjustment	☐ Option 11

4.20 Which treatment process(es) are used at the other facility to reduce pathogens in sewage sludge or reduce the vector attraction properties of sewage sludge before leaving the other facility? (Check all that apply.)

☐ Preliminary operations (e.g., sludge grinding and degritting)	☐ Thickening (concentration)
☐ Stabilization	☐ Anaerobic digestion
☐ Composting	☐ Conditioning
☐ Disinfection (e.g., beta ray irradiation, gamma ray irradiation, pasteurization)	☐ Dewatering (e.g., centrifugation, sludge drying beds, sludge lagoons)
☐ Heat drying	☐ Thermal reduction
☐ Methane or biogas capture and recovery	☐ Other (specify) _____

Surface Disposal Continued

Vector Attraction Reduction

4.21 Which vector attraction reduction option, if any, is met when sewage sludge is placed on this active sewage sludge unit?

☐ Option 9 (Injection below and surface)

☐ Option 10 (Incorporation into soil within 6 hours)

☐ Option 11 (Covering active sewage sludge unit daily)

☐ None

4.22 Describe any treatment processes used at the active sewage sludge unit to reduce vector attraction properties of sewage sludge.

☐ Check here if you have attached your description to the application package.

Groundwater Monitoring

4.23 Is groundwater monitoring currently conducted at this active sewage sludge unit, or are groundwater monitoring data otherwise available for this active sewage sludge unit?

☐ Yes

☐ No ➔ SKIP to Item 4.26 (Part 2, Section 4) below.

4.24 Provide a copy of available groundwater monitoring data.

☐ Check here to indicate you have attached the monitoring data.

4.25 Describe the well locations, the approximate depth to groundwater, and the groundwater monitoring procedures used to obtain these data.

☐ Check here if you have attached your description to the application package.

4.26 Has a groundwater monitoring program been prepared for this active sewage sludge unit?

☐ Yes

☐ No ➔ SKIP to Item 4.28 (Part 2, Section 4) below.

4.27 Submit a copy of the groundwater monitoring program with this permit application.

☐ Check here to indicate you have attached the monitoring program.

4.28 Have you obtained a certification from a qualified groundwater scientist that the aquifer below the active sewage sludge unit has not been contaminated?

☐ Yes

☐ No ➔ SKIP to Item 4.30 (Part 2, Section 4) below.

4.29 Submit a copy of the certification with this permit application.

☐ Check here to indicate you have attached the certification to the application package.

Site-Specific Limits

4.30 Are you seeking site-specific pollutant limits for the sewage sludge placed on the active sewage sludge unit?

☐ Yes

☐ No ➔ SKIP to Part 2, Section 5.

4.31 Submit information to support the request for site-specific pollutant limits with this application.

☐ Check here to indicate you have attached the requested information.

PART 2, SECTION 5 INCINERATION (40 CFR 122.21(q)(11))

Incineration

Incinerator Information

5.1 Do you fire sewage sludge in a sewage sludge incinerator?

☐ Yes ☑ No ➔ SKIP to END.

5.2 Indicate the total number of incinerators used at your facility. (Complete the remainder of Section 5 for each such incinerator.)

☐ Check here to indicate that you have attached information for one or more incinerators.

5.3 Incinerator name or number

Location address (street, route number, or other specific identifier)

County	County code ☐ Not available	
City or town	State	ZIP code

Latitude/Longitude of Incinerator (see instructions)

Latitude	Longitude
° ' "	° ' "

Method of Determination

☐ USGS map ☐ Field survey ☐ Other (specify) _____

Amount Fired

5.4 Dry metric tons per 365-day period of sewage sludge fired in the sewage sludge incinerator:

Beryllium NESHAP

5.5 Submit information, test data, and a description of measures taken that demonstrate whether the sewage sludge incinerated is beryllium-containing waste and will continue to remain as such.

☐ Check here to indicate that you have attached this material to the application package.

5.6 Is the sewage sludge fired in this incinerator "beryllium-containing waste" as defined at 40 CFR 61.31?

☐ Yes ☐ No ➔ SKIP to Item 5.8 (Part 2, Section 5) below.

5.7 Submit with this application a complete report of the latest beryllium emission rate testing *and* documentation of ongoing incinerator operating parameters indicating that the NESHAP emission rate limit for beryllium has been and will continue to be met.

☐ Check here to indicate that you have attached this information.

Mercury NESHAP

5.8 Is compliance with the mercury NESHAP being demonstrated via stack testing?

☐ Yes ☐ No ➔ SKIP to Item 5.11 (Part 2, Section 5) below.

5.9 Submit a complete report of stack testing and documentation of ongoing incinerator operating parameters indicating that the incinerator has met and will continue to meet the mercury NESHAP emission rate limit.

☐ Check here to indicate that you have attached this information.

5.10 Provide copies of mercury emission rate tests for the two most recent years in which testing was conducted.

☐ Check here to indicate that you have attached this information.

5.11 Do you demonstrate compliance with the mercury NESHAP by sewage sludge sampling?

☐ Yes ☐ No ➔ SKIP to Item 5.13 (Part 2, Section 5) below.

5.12 Submit a complete report of sewage sludge sampling and documentation of ongoing incinerator operating parameters indicating that the incinerator has met and will continue to meet the mercury NESHAP emission rate limit.

☐ Check here to indicate that you have attached this information.

Incineration Continued

Dispersion Factor

5.13	Dispersion factor in micrograms/cubic meter per gram/second:	
5.14	Name and type of dispersion model:	
5.15	Submit a copy of the modeling results and supporting documentation. ☐ Check here to indicate that you have attached this information.	

Control Efficiency

5.16 Provide the control efficiency, in hundredths, for each of the pollutants listed below.

Pollutant	Control Efficiency, in Hundredths
Arsenic	
Cadmium	
Chromium	
Lead	
Nickel	

5.17	Attach a copy of the results or performance testing and supporting documentation (including testing dates). ☐ Check here to indicate that you have attached this information.	

Risk-Specific Concentration for Chromium

5.18	Provide the risk-specific concentration (RSC) used for chromium in micrograms per cubic meter:	
5.19	Was the RSC determined via Table 2 in 40 CFR 503.43? ☐ Yes ☐ No ➔ SKIP to Item 5.21 (Part 2, Section 5) below.	
5.20	Identify the type of incinerator used as the basis. ☐ Fluidized bed with wet scrubber ☐ Other types with wet scrubber ☐ Fluidized bed with wet scrubber and wet electrostatic precipitator ☐ Other types with wet scrubber and wet electrostatic precipitator	
5.21	Was the RSC determined via Table 6 in 40 CFR 503.43 (site-specific determination)? ☐ Yes ☐ No ➔ SKIP to Item 5.23 (Part 2, Section 5) below.	
5.22	Provide the decimal fraction of hexavalent chromium concentration to total chromium concentration in stack exit gas:	
5.23	Attach the results of incinerator stack tests for hexavalent and total chromium concentrations, including the date(s) of any test(s), with this application. ☐ Check here to indicate that you have attached this information. ☐ Not applicable	

Incinerator Parameters

5.24	Do you monitor total hydrocarbons (THC) in the exit gas of the sewage sludge incinerator? ☐ Yes ☐ No	
5.25	Do you monitor carbon monoxide (CO) in the exit gas of the sewage sludge incinerator? ☐ Yes ☐ No	
5.26	Indicate the type of sewage sludge incinerator.	
5.27	Incinerator stack height in meters:	
5.28	Indicate whether the value submitted in Item 5.27 is (check only one response): ☐ Actual stack height ☐ Creditable stack height	

Incineration Continued

Performance Test Operating Parameters

5.29	Maximum performance test combustion temperature:	
5.30	Performance test sewage sludge feed rate, in dry metric tons/day	

5.31 Indicate whether value submitted in Item 5.30 is (check only one response):

☐ Average use ☐ Maximum design

5.32 Attach supporting documents describing how the feed rate was calculated.

☐ Check here to indicate that you have attached this information.

5.33 Submit information documenting the performance test operating parameters for the air pollution control device(s) used for this sewage sludge incinerator.

☐ Check here to indicate that you have attached this information.

Monitoring Equipment

5.34 List the equipment in place to monitor the listed parameters.

Parameter	Equipment in Place for Monitoring
Total hydrocarbons or carbon monoxide	
Percent oxygen	
Percent moisture	
Combustion temperature	
Other (describe)	

Air Pollution Control Equipment

5.35 List all air pollution control equipment used with this sewage sludge incinerator.

☐ Check here if you have attached the list to the application package for the noted incinerator.

END of PART 2

Submit completed application package to your NPDES permitting authority.

Generation of Sewage Sludge or Preparation of a Material Derived from Sewage Sludge Continued

Additional pages for backup receiving facility:

Shipment Off Site for Treatment or Blending

2.17 Does another facility provide treatment or blending of your facility's sewage sludge? (This question does not pertain to dewatered sludge sent directly to a land application or surface disposal site.)

☑ Yes ☐ No ➔ SKIP to Item 2.32 (Part 2, Section 2) below.

2.18 Indicate the total number of facilities that provide treatment or blending of your facility's sewage sludge. Provide the information in Items 2.19 to 2.26 (Part 2, Section 2) below for each facility.

☑ Check here if you have attached additional sheets to the application package.

1 primary, 1 backup

2.20 Total dry metric tons per 365-day period of sewage sludge provided to receiving facility: Contingent

2.21 Does the receiving facility provide additional treatment to reduce pathogens in sewage sludge from your facility or reduce the vector attraction properties of sewage sludge from your facility?

☑ Yes ☐ No ➔ SKIP to Item 2.24 (Part 2, Section 2) below.

2.22 Indicate the pathogen class and reduction alternative and the vector attraction reduction option met for the sewage sludge at the receiving facility.

Pathogen Class and Reduction Alternative	Vector Attraction Reduction Option
☐ Not applicable	☐ Not applicable
☐ Class A, Alternative 1	☐ Option 1
☐ Class A, Alternative 2	☐ Option 2
☐ Class A, Alternative 3	☐ Option 3
☐ Class A, Alternative 4	☐ Option 4
☑ Class A, Alternative 5	☑ Option 5
☐ Class A, Alternative 6	☐ Option 6
☐ Class B, Alternative 1	☐ Option 7
☐ Class B, Alternative 2	☐ Option 8
☐ Class B, Alternative 3	☐ Option 9
☐ Class B, Alternative 4	☐ Option 10
☐ Domestic septage, pH adjustment	☐ Option 11

Generation of Sewage Sludge or Preparation of a Material Derived from Sewage Sludge Continued

2.23 Which treatment process(es) are used at the receiving facility to reduce pathogens in sewage sludge or reduce the vector attraction properties of sewage sludge from your facility? (Check all that apply.)

- ☐ Preliminary operations (e.g., sludge grinding and degritting)
- ☐ Thickening (concentration)
- ☐ Stabilization
- ☐ Anaerobic digestion
- ☑ Composting
- ☐ Conditioning
- ☐ Disinfection (e.g., beta ray irradiation, gamma ray irradiation, pasteurization)
- ☐ Dewatering (e.g., centrifugation, sludge drying beds, sludge lagoons)
- ☐ Heat drying
- ☐ Thermal reduction
- ☐ Methane or biogas capture and recovery
- ☐ Other (specify) _____

2.24 Attach a copy of any information you provide the receiving facility to comply with the "notice and necessary information" requirement of 40 CFR 503.12(g).

☐ Check here to indicate that you have attached material.

2.25 Does the receiving facility place sewage sludge from your facility in a bag or other container for sale or give-away for application to the land?

☐ Yes ☑ No ➔ SKIP to Item 2.32 (Part 2, Section 2) below.

2.26 Attach a copy of all labels or notices that accompany the product being sold or given away.

☐ Check here to indicate that you have attached material.

☑ Check here once you have completed Items 2.17 to 2.26 (Part 2, Section 2), then ➔ SKIP to Item 2.32 (Part 2, Section 2) below.

Treatment Process Narrative

Existing Treatment Process

Big Bear Area Regional Wastewater Agency (BBARWA) is a joint powers authority consisting of Big Bear City Community Services District, City of Big Bear Lake, and San Bernardino County Service Area 53-B[1]. BBARWA owns and operates a regional Wastewater Treatment Plant (WWTP). The WWTP treats commercial and domestic wastewater from these three collection systems.

The existing WWTP has a design capacity of 4.89 million gallons per day (MGD). The existing treatment process includes the following:

- Preliminary treatment consisting of a mechanical coarse screen and an aerated grit chamber;
- Secondary treatment consisting of extended aeration oxidation ditches and secondary clarifiers; and
- Solids handling through a dewatering belt filter press.

Treated effluent is temporarily stored on-site prior to discharge to Lucerne Valley. Dewatered solids are hauled off-site.

Future Upgraded Treatment Process

As part of the Replenish Big Bear Program, proposed upgrades to the BBARWA WWTP include:

- Biological nutrient removal added to the existing oxidation ditches;
- Tertiary filtration and nutrient removal via denitrification filters, ultrafiltration (UF), and reverse osmosis (RO) membrane filtration;
- Brine pellet reactor for brine minimization; and
- Ultraviolet (UV) disinfection processes.

The new facilities would be designed for a treatment capacity of 2.2 MGD, with operational capabilities to divert a portion of the denitrification filter effluent directly to ultraviolet disinfection depending on effluent water quality targets and treatment performance. However, it is anticipated that 100% of the water discharged will be treated with RO and UV disinfection. The anticipated completion date is mid-2026.

Solids generated through the brine pellet reactor would be disposed off-site and the liquid stream reject from the brine pellet reactor process would be conveyed to brine evaporation ponds on-site at the BBARWA WWTP for drying and disposal. Treated effluent would be discharged to Shay Pond and Stanfield Marsh, which flows into Big Bear Lake. BBARWA is planning to maintain its current discharge location in Lucerne Valley, where undisinfected secondary effluent is currently used to irrigate fodder crops used for livestock feed. The dewatered solids would continue to be hauled off-site.

[1] BBARWA owns and maintains the trunk lines and force main pump station to convey flows from CSA 53B to the WWTP, but CSA 53B maintains their own collection system.

A detailed summary of the treatment process upgrades is shown in **Table 1**.

Table 1. Summary of Treatment Process Upgrades

Treatment Mode	Processes
Biological Nutrient Removal	**Nitrification-Denitrification**: Retrofit existing oxidation ditches to a Modified Ludzack-Ettinger (MLE) configuration with turbo blowers and diffused aeration for nitrogen removal.
Tertiary Filtration & Nutrient Removal	**Denitrification Filter:** Construct denitrification filters for nitrogen and phosphorus removal. Chemical provisions for supplemental carbon and chemical precipitant addition will be provided for denitrification and phosphorus removal, respectively.
Membrane Filtration	**Ultrafiltration and Reverse Osmosis:** Construct skid-mounted pressurized UF membranes and RO membrane facilities capable of high recovery, high TDS removal, and removal of residual nutrients. Chemical provisions for antiscalant, pH adjustment, and remineralization chemicals will be provided. Brine from the RO system will be conveyed to the Pellet Reactor for brine minimization.
Disinfection	**UV Disinfection:** Construct closed vessel UV disinfection unit process for disinfection of denitrification filter effluent or RO permeate water. UV design criteria such as UV transmittance and UV dose are dependent on the quality of the feed water.
Brine Minimization	**Pellet Reactor:** Construct a skid-mounted pellet reactor system which provides brine minimization through additional RO membrane filtration and precipitation of partially soluble salts through a fluidized bed reactor.

The projected effluent quality of the proposed discharge is presented in **Table 2** for the constituents of interest.

Table 2. Summary of Projected Effluent Quality

Constituent	Projected Effluent Quality	Units
Ammonia as N	0.05	mg/L
Boron	0.11	mg/L
Chloride	0.60	mg/L
Fluoride	<0.026[a]	mg/L
Hardness, Total (as CaCO3)	3.20	mg/L
MBAS	0.0014	mg/L
Sodium	1.9	mg/L
Sulfate	0.20	mg/L
Total Dissolved Solids (TDS)	50	mg/L
Total Inorganic Nitrogen (TIN)	0.10	mg/L-N
Total Nitrogen (TN)	0.60	mg/L-N

Constituent	Projected Effluent Quality	Units
Chlorophyll-a[b]	N/A	µg/L
Total Phosphorus (TP)	0.03	mg/L-P
Chlordane	<0.17[a]	µg/L
4,4'-DDT	<0.0052[a]	µg/L
PCBs	<2.5[a]	µg/L
Cadmium	<0.11[a]	µg/L
Copper	0.07	µg/L
Lead	0.01	µg/L
Mercury	<0.05[a]	ng/L
Aluminum	1.3	µg/L
Specific Conductance	18	µmhos/cm

[a] The projected effluent quality is anticipated to be below the detection limit.
[b] Chlorophyll a is not a constituent that will be discharged by the BBARWA WWTP.

Service, Quality, Community

Executive Summary

The Big Bear Area Regional Wastewater Agency (BBARWA) operates an existing regional wastewater treatment plant (WWTP) and related facilities in the Big Bear Valley (Valley). BBARWA has partnered with Big Bear City Community Service District (BBCCSD), Big Bear Lake Department of Water and Power (BBLDWP), Big Bear Municipal Water District (BBMWD), and Bear Valley Basin Groundwater Sustainability Agency (BVBGSA), collectively known as the Agency Team, to develop the Replenish Big Bear Program. The Replenish Big Bear Program is intended to help protect the Valley and the Santa Ana Watershed from the impacts of drought and variable precipitation by recovering a water resource currently discharged outside of the watershed. The program is comprised of several elements; the first project includes treatment upgrades at the BBARWA WWTP to produce disinfected advanced treated effluent by providing tertiary filtration, reverse osmosis (RO) treatment and ultraviolet (UV) disinfection for 100% of the water discharged to Stanfield Marsh Wildlife and Waterfowl Preserve (Stanfield Marsh), a tributary of Big Bear Lake (Lake) and a separate discharge to Shay Pond, a tributary of Shay Creek. These discharges are referred to as the "Lake Discharge" and the "Shay Pond Discharge."

The purpose of this technical memorandum (TM) is to provide a structure for issuing a National Pollutant Discharge Elimination System (NPDES) permit for the BBARWA WWTP to Stanfield Marsh and subsequently to the Lake in the context of the Big Bear Lake Nutrient Total Maximum Daily Load (Nutrient TMDL) for Dry Hydrologic Conditions (Resolution No. R8-2006-0023).

The proposed approach to providing the rationale for permitting the Lake Discharge includes:

1) Demonstrating how the Lake Discharge, in conjunction with requirements for other responsible parties in the Nutrient TMDL, will support attaining the numeric targets in the Nutrient TMDL and, by extension, the applicable water quality standards addressed by the TMDL; and

2) Identifying total phosphorus (TP) water quality based effluent limitations (WQBELs) that can be assigned to be consistent with the assumptions of the Nutrient TMDL.

To evaluate how the Lake Discharge impacts the attainment of numeric targets in the Lake, the impacts were simulated using a two-dimensional hydrodynamic-water quality model (CE-QUAL-W2) of Big Bear Lake developed by Dr. Michael A. Anderson (2021 Lake Model Analysis) and updated in 2022. The 2021 Lake Model Analysis and 2022 Lake Model Update demonstrated that the Lake Discharge will likely result in lower concentrations of TP and chlorophyll-a as compared to the baseline conditions without the project and will increase Lake levels, reducing the amount of time critical conditions occur in the Lake.

To develop an NPDES permit for the Lake Discharge, TP WQBELs must be developed that are consistent with the assumptions of the Nutrient TMDL. The Nutrient TMDL does not include a TP allocation for the Lake Discharge for dry hydrologic conditions. As a result, to be consistent with the Nutrient TMDL assumptions, the Lake Discharge, in essence, needs to have a zero TP wasteload allocation (WLA) during dry hydrologic conditions and not contribute to exceedances of the numeric targets year-round.

To be consistent with the Nutrient TMDL assumptions, TP WQBELs could be established as a combination of a WQBEL derived from the TP numeric targets and an offset framework that would result in a net zero TP loading (or zero TP WLA) to the Lake. The TP loads added to the Lake by the Lake Discharge will be offset through triennial alum applications to attain net zero TP loadings for the upcoming three years. In the event of extreme runoff (defined here as exceeding about 25,000 acre-feet per year (AFY)[1]), which has the potential to bury the reactive alum cap on the sediments and reduce its effectiveness, an alum treatment will be conducted that following spring-summer and the triennial treatment schedule will be reset.

Should the Nutrient TMDL be modified in the future by the Santa Ana Regional Water Quality Control Board (Regional Water Board), allocations for the Lake Discharge could be included and the TP offset program could potentially be discontinued. However, the approach outlined in this TM will provide the justification for issuing an NPDES permit without the need for a TMDL modification.

1 Background

The purpose of this TM is to provide a structure for issuing an NPDES permit for the BBARWA WWTP discharge to Stanfield Marsh, and subsequently to the Lake in the context of the Nutrient TMDL for Dry Hydrologic Conditions (Resolution No. R8-2006-0023).

1.1 TMDL Summary

The Nutrient TMDL was adopted by the Regional Water Board on April 21, 2006 and became effective on September 25, 2007. Upon adoption, the Nutrient TMDL was incorporated into Section 6 of the Water Quality Control Plan for the Santa Ana Region (Basin Plan). The Nutrient TMDL includes targets for TP, macrophyte coverage, nuisance aquatic vascular plant species, and chlorophyll-a in the Lake (see **Table 1**). The targets are designated as numeric interpretations of Basin Plan water quality objectives. Because the targets are TMDL equivalents of water quality objectives that apply at all times, the targets apply to all hydrologic conditions. However, the loads necessary to meet those numeric targets were only calculated under dry hydrologic conditions, as discussed further below.

Table 1. Nutrient TMDL Numeric Targets

Indicator	Target Value [a][b]
TP Concentration [c]	Annual average no greater than 35 µg/L
Macrophyte Coverage[d]	30-40% on a total lake area basis
Percentage of Nuisance Aquatic Vascular Plant Species[d][e]	95% eradication on a total area basis of Eurasian Water milfoil and any other invasive aquatic plant species
Chlorophyll-a Concentration[e]	Growing season average no greater than 14 µg/L

Source: Basin Plan

Notes:

a) Targets to be attained no later than 2015 (dry hydrological conditions), 2020 (all other conditions)

b) Compliance date for wet and/or average hydrological conditions may change in response to approved TMDLs for wet/average hydrological conditions.

c) Annual average determined by the following methodology: the nutrient data from both the photic composite and discrete bottom samples are averaged by station number and month; a calendar year average is obtained for each sampling location by averaging the average of each month; and finally, the separate annual averages for each location are averaged to determine the lake-wide average.

d) Calculated as a 5-yr running average based on measurements taken at peak macrophyte growth.

e) Growing season is the period from May 1 through October 31 of each year. The chlorophyll-a data from the photic samples are averaged by station number and month; a growing season average is obtained for each sampling location by averaging the average of each month; and finally, the separate growing season averages for each location are averaged to determine the lake-wide average.

As discussed in the Nutrient TMDL, a "*weight of evidence*" approach will be used to assess attainment of the numeric targets. This means that data pertaining to all targets will be assessed and not attaining one target will not automatically imply that the Lake is not attaining the TMDL (Basin Plan page 6-119).

The Nutrient TMDL also assigns TP WLA to point sources (urban runoff) and load allocations (LA) to non-point sources that were identified as contributing TP loads to the Lake at the time the TMDL was developed. Per the Resolution adopting the Basin Plan Amendment (BPA) that incorporated the Nutrient TMDL into the Basin Plan,

> "*The TMDL for Dry Hydrological Conditions specifies a reduction in phosphorus from internal nutrient sources, which are lake sediment and macrophytes…. The TMDL for Dry Hydrological Conditions does not specify nutrient reductions from external watershed sources, which include resorts, urban discharges and open space/forested lands.*"

Therefore, one of the primary assumptions of the Nutrient TMDL is that the largest sources of TP to the Lake are lake sediment and macrophytes, and external watershed source contributions are minimal compared to those sources. External watershed sources are not required to reduce loads during the dry hydrologic condition (**Table 2**).

The Nutrient TMDL allocations only apply during dry hydrologic conditions, defined as average tributary inflow to the Lake ranging from 0 to 3,049 acre feet (AF), average lake levels ranging from 2,033 to 2,052 meters, and annual precipitation ranging from 0 to 23 inches. The baseline loads, allocations, and responsible parties for achieving the allocations during dry hydrologic conditions are summarized in **Table 2.**

Table 2. Nutrient TMDL WLA and LA for Dry Hydrological Conditions

Source	Baseline Load TP (lbs/yr)	TP Allocation (lbs/yr)	Percent Load Reduction	TMDL Assigned Responsible Parties
WLAs				
Urban	475	475	0%	Department of Transportation (Caltrans), the County of San Bernardino, San Bernardino County Flood Control District, the City of Big Bear Lake

Internal Sediment	17,943	8,555	52%	US Forest Service, Caltrans, the County of San Bernardino, San Bernardino County Flood Control District, the City of Big Bear Lake, and Big Bear Mountain Resorts[a]
Internal Macrophyte	21,388	15,700	27%	
Atmospheric Deposition	1,074	1,074	0%	N/A-Background
Forest	175	175	0%	US Forest Service
Resort	33	33	0%	Big Bear Mountain Resorts
Total	**41,088**	**26,012**	**37%**	

Source: Basin Plan
Notes:
a) The Nutrient TMDL requires the responsible parties to submit a Lake Management Plan for Big Bear Lake to address the non-point source LAs.

1.2 Relationship of the Project to the TMDL

The Agency Team is planning the Replenish Big Bear Program, which was developed to help protect the Valley and the Santa Ana Watershed from the impacts of drought and variable precipitation by recovering a water resource currently discharged outside of the watershed. The Replenish Big Bear Program is comprised of three independent projects, which may be implemented separately, when appropriate:

1) WWTP upgrades and effluent discharge to Stanfield Marsh (and subsequently to the Lake) and a separate discharge to Shay Pond;

2) Use of Lake water for landscape irrigation, construction uses and snowmaking; and

3) Use of Lake water for groundwater recharge in Sand Canyon.

The first project includes treatment upgrades at the BBARWA WWTP to produce disinfected advanced treated effluent by providing tertiary filtration, RO treatment and UV disinfection for 100% of the water discharged to the Lake and to Shay Pond. The proposed upgrades to the BBARWA WWTP include:

- Biological nutrient removal improvements to the existing oxidation ditches for improved nitrification and denitrification;
- Tertiary filtration and nitrogen and phosphorus removal via denitrification filters;
- Low- and high-pressure filtration with ultrafiltration (UF) membranes and 90% recovery RO membranes;
- Brine pellet reactor for brine minimization to produce a total system recovery of 99%; and
- UV disinfection.

The proposed upgrades (i.e., new advanced treatment train) would be designed for a treatment capacity of 2.2 million gallons per day (MGD). By 2040, accounting for expected growth, it is estimated that the WWTP could produce 2,210 AFY of advanced treated effluent, assuming a 99% total recovery rate could be achieved (90% RO recovery and 90% recovery of brine through brine minimization). The WWTP currently produces about 2.0 MGD of undisinfected secondary effluent on an average annual basis.

For this TM, the disinfected advanced treated effluent discharge to Stanfield Marsh and subsequently to the Lake is the focus of the analysis. **Table 3** shows the maximum design flow rate and TP concentration and loading for the Lake Discharge. While a portion of the total flow (up to 80 AFY) may be discharged to Shay Pond instead of Stanfield Marsh, this analysis is based on discharging 100% of the treated effluent to Stanfield Marsh to be conservative.

Table 3. Lake Discharge Proposed Max Discharge Flow Rate, TP Concentration and Loading

Parameter	Target Value
Proposed TP Concentration (mg/L)	0.03
Proposed Max Design Flow (MGD)	2.2
Proposed Max TP Discharge Load (lbs/yr)	200

The Lake Discharge will discharge approximately 200 lbs/yr of TP to the Lake, assuming the maximum discharge rate of 2.2 MGD at 0.03 mg/L. As discussed in the Nutrient TMDL Background section, the total loading capacity during dry hydraulic conditions is 26,012 lbs/yr of TP. The Lake Discharge will therefore add less than 1% of the total TP loading capacity to the Lake during dry hydrologic conditions and even less during other hydrologic conditions. In contrast, non-point sources, such as legacy in-lake sediments, contribute the majority of the TP loading to the Lake.

BBARWA WWTP previously held an NPDES permit for discharge to Stanfield Marsh, a tributary to the Lake (Order No. 00-12 NPDES No. CA8000344). In 2004, BBARWA submitted

a Report of Waste Discharge (ROWD) that noted the Stanfield Marsh discharge location was no longer being used and that the WWTP no longer had any discharges to Waters of the United States. Based on the ROWD, in 2005, the NPDES permit was determined to no longer be necessary and was replaced by Waste Discharge Requirements (WDRs) for the Lucerne Valley discharge location (Order R7-2021-0023).

Given that the BBARWA WWTP was not discharging to the Lake or its tributaries at the time of TMDL development, it was not assigned a TP allocation in the Nutrient TMDL. Additionally, the Nutrient TMDL fully assigned the identified TP loading capacity during dry hydrologic conditions to other sources. As a result, under dry hydrologic conditions, no unallocated TP loading capacity is available in the Nutrient TMDL for the BBARWA WWTP to be allocated for the Lake Discharge. Under other hydrologic conditions, the Nutrient TMDL allocations do not apply and loading capacity may be available to assign to the Lake Discharge. As noted in the Nutrient TMDL and in the Staff Report, greater lake volume and dilution is anticipated under wetter conditions.[2]

As discussed in the Nutrient TMDL, the Regional Water Board intends to revise the Nutrient TMDL in the future to address other hydrologic conditions. When the Nutrient TMDL is revised, TP allocations for the Lake Discharge can be incorporated. However, the Nutrient TMDL modifications may not occur until after the Lake Discharge begins. The purpose of this TM is to provide a structure for issuing an NPDES permit for the Lake Discharge assuming the TMDL has not been revised to incorporate TP allocations for the Lake Discharge prior to NPDES permit issuance.

2 Proposed Approach

When a TMDL exists for a waterbody, the Clean Water Act (CWA) and associated regulations require that the permit contain WQBELs that are "*consistent with the assumptions and requirements of any available wasteload allocation for the discharge*" (40 Code of Federal Regulations (C.F.R.) § 122.44(d)(1)(vii)(B)). Additionally, United States Code (U.S.C.) § 1313(d)(4)(A) notes that WQBELs associated with a TMDL can be revised if the cumulative effect of all WQBELs will assure attainment of the water quality standard. In general, WQBELs must be "*derived from and comply with*" all applicable water quality standards. (40 C.F.R. § 122.44(d)(1)(vii)(A).)

The key requirements for the permit are therefore that the WQBELs be consistent with the assumptions of the TMDL and that the cumulative effect of all of the limitations for the sources identified in the TMDL assure attainment of the water quality standards addressed

[2] "*Indeed, since the TMDL for dry hydrological conditions was developed to meet the targets under the critical, worst-case conditions, consistent compliance with these targets is expected to be achieved even in the absence of TMDLs for wet/average hydrological conditions, given the greater lake volume and dilution anticipated under wetter conditions.*" (Basin Plan, page 6-119)

by the TMDL. To address these requirements, the proposed approach to providing the rationale for permitting the Lake Discharge includes:

1) Demonstrating the Lake Discharge will support attaining the numeric targets in the Nutrient TMDL and by extension the applicable water quality standards addressed by the TMDL; and

2) Identifying TP WQBELs that can be assigned to be consistent with the assumptions of the Nutrient TMDL.

2.1 Demonstrating Lake Discharge Will Support Attainment of Nutrient TMDL Numeric Targets

To evaluate how the Lake Discharge could support the attainment of numeric targets in the Lake, the impacts were simulated in the 2021 Lake Model Analysis and a subsequent 2022 Lake Model Update. The relevant results of the modeling are summarized in **Section 4** and the complete results are provided in the reports entitled *Big Bear Lake Analysis: Replenish Big Bear Draft Final Report* (referred to as 2021 Lake Model Analysis; Anderson 2021) and Replenish Big Bear: Modeling of Higher Flows and with Zero TP Load (referred to as 2022 Lake Model Update, Anderson, 2022). The 2021 Lake Model Analysis and 2022 Lake Model Update demonstrated that the Lake Discharge will likely result in lower concentrations of TP and chlorophyll-a as compared to the baseline conditions without the project, particularly during dry hydrologic conditions. These reports are included in the Antidegradation

2.2 Identifying TP WQBELs Consistent with Assumptions of Nutrient TMDL

As discussed in the Background section, the Nutrient TMDL does not include a TP allocation for the Lake Discharge for dry hydrologic conditions. As a result, to be consistent with the Nutrient TMDL assumptions, the Lake Discharge in essence needs to have a zero TP WLA during dry hydrologic conditions and not contribute to exceedances of the numeric targets year-round. To be consistent with the Nutrient TMDL assumptions, TP WQBELs could be established as a combination of a TP WQBEL derived from the TMDL numeric targets and an offset framework that would result in a net zero TP loading (or zero TP WLA) to the Lake.

To address the lack of TP allocations in the TMDL during dry hydrologic conditions, the TP loads added to the Lake by the Lake Discharge will be offset through triennial alum applications to attain net zero TP loadings for the upcoming three years. In the event of extreme runoff (defined here as exceeding about 25,000 AFY[3]), which has the potential to bury the reactive alum cap on the sediments and reduce its effectiveness, an alum

[3] Approximately the 80th percentile annual inflow based on WaterMaster data for 1977-2018.

treatment will be conducted that following spring-summer and the triennial treatment schedule will be reset.

Should the TMDL be modified in the future by the Regional Water Board, TP allocations for the Lake Discharge could be included and the offset program could potentially be discontinued. However, the approach outlined above will provide the justification for issuing an NPDES permit without the need for a TMDL modification.

3 Demonstration that the Lake Discharge Will Support Attainment of Nutrient TMDL Numeric Targets in the Lake as Compared to Baseline Conditions

The 2021 Lake Model Analysis was used to evaluate the impact of the Lake Discharge on the Lake as compared to the water quality that would be predicted without the project. The 2021 Lake Model Analysis considered the impact of the Lake Discharge on lake levels, TP, chlorophyll-a and aquatic plants. The 2021 Lake Model Analysis simulated the period 2009 to 2019 with the Lake Discharge as compared to the baseline from that period and predicted future conditions through 2050 for TP and chlorophyll-a. The 2021 Lake Model 2009 to 2019 baseline analysis reflects the impacts of actions taken to date to implement the Nutrient TMDL. The predicted future conditions do not reflect any additional actions that may be taken by the responsible parties to attain the Nutrient TMDL requirements or the impacts of the offset program described above.

For the future model scenarios, the 2021 Lake Model Analysis presented results for three hydrologic conditions 1) 5th -percentile corresponded to an average inflow rate of 8,646 acre feet per year (AFY) and represents extended drought, 2) 50th -percentile (median) corresponded to intervals of both high runoff and drought comparable to 2009-2019 (average annual inflow of 10,595 AFY), and 3) 95th percentile represented a period of protracted above average rainfall and runoff (average annual inflow of 12,225 AFY). The 5th -percentile hydrologic conditions most closely reflect the dry hydrologic conditions determined to be the critical condition for the Nutrient TMDL and are therefore the focus of the discussion.

For the current model scenarios, the 2021 Lake Model Analysis predicted that the Lake Discharge would result in similar or lower TP concentrations in the Lake on average as compared to baseline conditions. For the time period 2009-2019, the 2021 Lake Model Analysis predicted that the Lake Discharge would result in concentrations similar to or lower than the chlorophyll-a concentrations and aquatic plants under the baseline conditions on average (see **Table 4**).[4]

[4] See 2021 Lake Model Analysis Report (**Attachment A**) pages 47, 48, 56, 58, 59 and 60 for more detailed discussion of the results. The presented results correspond with Alternative 3 in the 2021 Lake Model Analysis. Note that the 2021 Lake Model Analysis Report presents chlorophyll-a values as average annual, which are lower than the growing season average due to the inclusion of winter values.

Table 4. Average Annual Predicted Concentrations of TP, Chlorophyll-a and Plants for 2009-2019 Period under Baseline Scenario and with Replenish Big Bear Project.

Scenario	TP (mg/L)	Chlorophyll-a (µg/L)[a]	Plants (g/m2)
Baseline (without Project)	0.037	9.3	106.9
With Replenish Big Bear Project	0.035	7.1	103.1

For the future long term scenarios, the 2021 Lake Model Analysis predicted the Lake Discharge would result in similar to or slightly lower TP and chlorophyll-a concentrations for the 5th-percentile hydrologic condition as compared to simulations without the Lake Discharge (aquatic plants were not evaluated in the future model scenarios) (see **Table 5**). [5]

Table 5. Long-Term Median Predicted Concentrations of TP and Chlorophyll-a for 5th-Percentile (Extreme Drought) Hydrologic Condition under the Baseline Scenario and with the Replenish Big Bear Project (TP Expressed as Annual Average Concentrations; Chlorophyll-a Shown as Growing Season Average Concentrations).

Scenario	TP (mg/L)	Chlorophyll-a (µg/L)[a]
Baseline (without Project)	0.055	14.2
With Replenish Big Bear Project	0.046	11.3

Notes:

a) The 2021 Lake Model Analysis Report presents chlorophyll-a values as annual average, which is lower than the growing season average due to the inclusion of winter values. The data shown in this table was extracted from the 2021 Lake Model Analysis results to represent the growing season average only. Growing season is the period from May 1 through October 31 of each year.

After the development of the 2021 Lake Model Analysis, additional scenarios were completed in 2022 to investigate the impacts of a higher discharge volume, account for WWTP discharge seasonal variability, and assess the impacts of a TP Offset Program on

[5] Under other hydrologic conditions, the Lake Model predicted that the median concentrations of TP would be similar to or lower than the baseline condition, but that chlorophyll-a concentrations may be slightly higher than the baseline condition with the Project. However, the predicted median chlorophyll-a concentrations under these conditions would be lower than the numeric TMDL target. Further analysis was conducted to evaluate these results (see **Table 7**).

the attainment of the Nutrient TMDL numeric targets. The TP Offset Program results are discussed in **Section 4**.

Recent engineering work indicates that higher discharge flows, up to 2,210 AFY, can be attained by employing additional brine minimization technology (**Table 1**). Note that the 2021 Lake Model Analysis assumed steady annual flows of 1,920 AFY, as it excluded the 80 AFY that could be discharged to Shay Pond. For the 2022 Lake Model Update, to be conservative, the additional analysis assumed all of the disinfected advanced treated effluent produced is discharged to the Lake.

Table 6. Initial and Updated Lake Discharge Flow Projections

Scenario	Lake Discharge Inflow (AFY)	Daily Lake Discharge Inflow (MGD)
Baseline	0	0
2021 Lake Model Analysis – Alternative 3 [(a)]	1920	1.71
2022 Update High Flow (99% recovery) [(b)]	2210	1.57 – 2.18
2022 Update Mid Flow (90% recovery) [(b)]	2009	1.42 – 1.98

Notes:

a) The total Replenish Big Bear production in the 2021 Lake Model Analysis was assumed to be 2,000 AFY with 80 AFY going to Shay Pond.

b) The 2022 Lake Model Update was based on all of the advanced treated effluent being discharged to the Lake under two different total recovery rate scenarios, with no discharge to Shay Pond.

Moreover, deliveries are expected to vary seasonally (**Figure 1**), thus varying from the 2021 Lake Model Analysis that assumed a uniform Lake Discharge of 1.71 MGD throughout the year. Inflows to BBAWRA are lower in the summer months due to reduced inflow and infiltration.

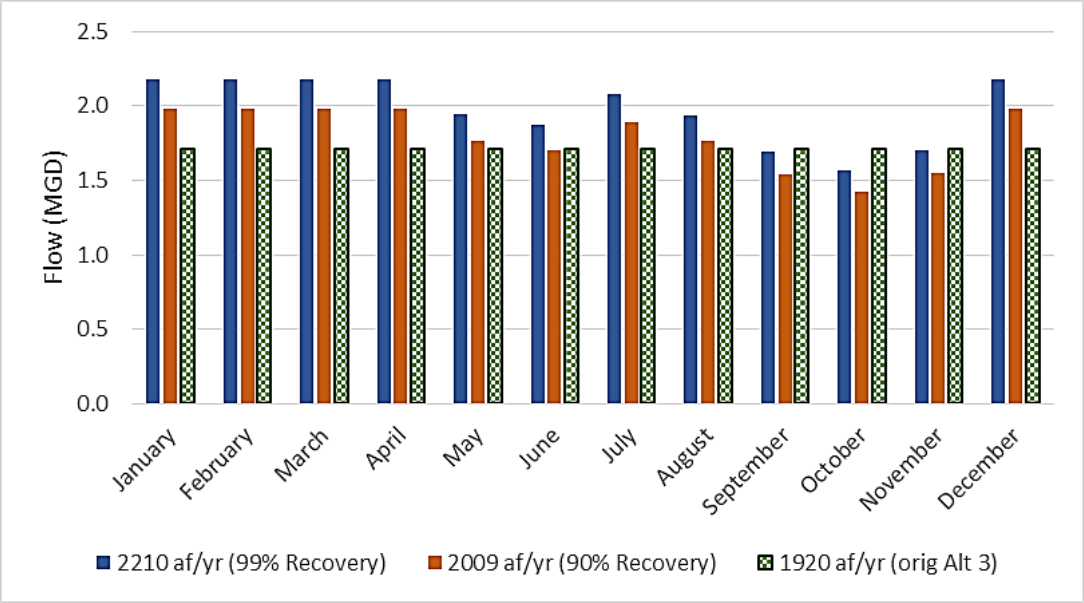

Figure 1. Monthly Flow Rates (Projected 2040) for Replenish Big Bear under Three Project Inflow Scenarios.

The 50th percentile hydrologic scenario for 2009-2050 was used in the additional analysis, noting that it includes a wide array of runoff conditions, including extended drought and periods of high runoff and was predicted to have slightly higher chlorophyll-a concentrations in the 2021 Lake Model Analysis. All other hydrologic, meteorological, biological, chemical and sedimentological factors, variables and conditions were identical to those used in prior simulations of long-term future conditions (Anderson, 2021)[6].

Long-term average predicted concentrations of TP and chlorophyll-a were lower with the Lake Discharge compared with predicted baseline conditions (**Table 7**). Baseline conditions were predicted to yield growing-season average chlorophyll-a concentration that slightly exceeded (by 0.1 µg/L) the TMDL target value of 14 µg/L, the 2021 Lake Model Analysis matched the target, and larger Lake Discharges that varied seasonally (**Figure 1**) yielded values below baseline and TMDL target values (**Table 7**).

[6] Anderson, M.A. 2021. *Big Bear Lake Analysis: Replenish Big Bear.* Final Report. 65 pp.

Table 7. Long-Term Average Predicted Concentrations of TP and Chlorophyll-a in Big Bear Lake under Different Operational Scenarios (TP Expressed as Annual Average Concentrations; Chlorophyll-a Shown as Growing Season Average Concentrations)

Operational Scenario (all at 50th percentile hydrology)	TP (mg/L)	Chlorophyll-a (µg/L)
TMDL target	***0.035***	***14.0***
Baseline	0.0477	14.1
1920 AFY (2021 Lake Model Analysis)	0.0433	14.0
2210 AF (99% recovery)	0.04.3	13.1
2009 AF (90% recovery)	0.0434	12.9

Based on the analysis provided by the 2021 Lake Model Analysis and the 2022 Lake Model Update, the Lake Discharge appears likely to improve water quality and increase the amount of time that the Lake would be meeting the water quality targets. In particular, the Lake Discharge is predicted to improve water quality during the dry hydrologic conditions that were determined to be the critical conditions for the TMDL.

Additionally, the 2021 Lake Model Analysis determined that the Lake Discharge would increase Lake levels by an average of two meters and significantly increase the lake volume. This increase results in the Lake levels being higher than the lake levels associated with the TMDL dry hydrologic condition (2,033 to 2,052 m) over 50% of the time during the model conditions associated with drought conditions and rarely falling below 2,052 m during other hydrologic conditions. In contrast, without the project, the Lake levels would be associated with the TMDL dry hydrologic condition approximately 85% of the time during extended drought conditions and between 20 and 45% of the time during other hydrologic conditions (see **Figure 2**). As noted in the Nutrient TMDL, the dry hydrologic conditions are considered to be the critical conditions for the Lake. The Lake Discharge will therefore also support attainment of the numeric targets by reducing the amount of time the critical conditions occur in the Lake.

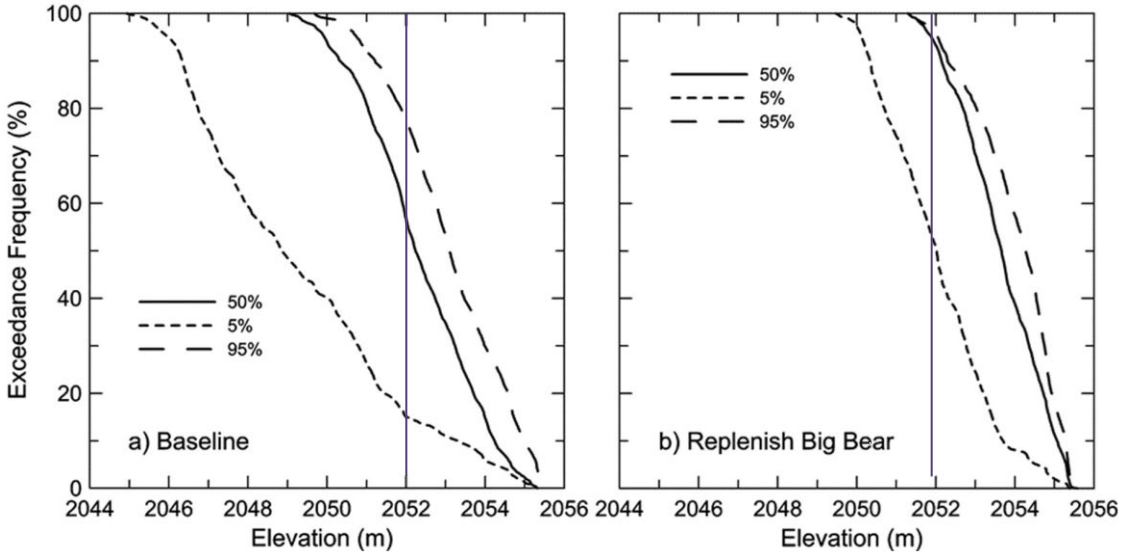

Figure 2. Predicted Lake Elevations at 5th-, 50th- and 95th Percentile Hydrologic Scenarios for a) Baseline Conditions and b) with the Lake Discharge. Vertical Lines Represent Upper Boundary for Lake Level under "Dry Hydrologic Condition".

4 Identifying TP WQBELs Consistent With the Assumptions of the Nutrient TMDL

Given that the Lake Discharge is predicted to improve conditions in the Lake, it is possible to determine an approach to assigning WQBELs without modifying the TMDL. The proposed approach is to include TP WQBELs consistent with the Nutrient TMDL TP numeric target and a TP offset framework. The TP offset framework will reduce TP loads by an amount equal to the Lake Discharge TP load, thereby resulting in a "net zero" TP load discharged to the Lake. This section describes the rationale for the approach to setting the TP WQBELs and the proposed offset program.

4.1 Background for Using Offsets in the Context of TMDLs

In 2005, the State Water Board developed "*A Process for Addressing Impaired Waters in California*" (Impaired Waters Policy). Appendix B to the Impaired Waters Policy compiled legal memorandums relevant to TMDLs. One of the memorandums is entitled "*Legal Authority for Offsets, Pollutant Trading, and Market Programs to Supplement Water Quality Regulation in California's Impaired Waters*" (State Water Board Offset Memo – see **Attachment A**) and provides a comprehensive discussion of the basis for establishing offsets in NPDES permits for waters that have TMDLs. While the memo was developed in 2001, the fundamental authorities remain and can be applied to permitting the Lake Discharge.

As noted in the State Water Board Offset Memo,

> *"When a TMDL is in place, the Clean Water Act (CWA) and California law give wide latitude to develop creative means of achieving compliance with water quality standards (WQS), subject to certain limitations."*
>
> *"Specifically, if the water is impaired, existing WQBELs may be relaxed if "the cumulative effect of all such revised effluent limitations based on such [TMDL] or waste load allocation will assure attainment of such [WQS]." (33 U.S.C. § 1313(d)(4)(A).)"*
>
> *"Federal regulations bolster these provisions. Under the regulations, WQBELs must be "consistent with the assumptions and requirements of any available wasteload allocation . . . ." (40 C.F.R. § 122.44(d)(1)(vii)(B).) The regulations do not require WQBELs to be "equivalent to" available waste load allocations. Accordingly, so long as the cumulative effect of all WQBELs assures attainment of WQS, hence the assumptions of the TMDL, WQBELs can be adjusted based upon whatever mechanisms the state determines is appropriate."*

The rationale outlined in the State Water Board Offset Memo for allowing offsets in the context of a TMDL is as follows:

1) Per Federal regulations implementing the CWA, WQBELs to implement a TMDL do not have to be equivalent to the available WLA as long as they are consistent with the assumptions in the TMDL.
2) As long as the cumulative effect of all effluent limitations assures attainment of water quality standards, the WQBELs can be calculated in any way the Regional Water Board determines to be appropriate.

Using offsets is an appropriate method for developing WQBELs for TP for the Lake Discharge because the result would be consistent with the assumptions of the Nutrient TMDL, as further described below.

4.2 Rationale for Assigning WQBELs

The Nutrient TMDL establishes a causal numeric target for TP of 0.035 mg/L as an annual average. As required by the CWA, TMDL numeric targets should be set at levels that will result in protection of beneficial uses and attainment of water quality standards. The Lake Discharge is currently anticipated to have an average discharge concentration of 0.03 mg/L TP, which is below the TMDL numeric target. Therefore, the proposed Lake Discharge quality would be consistent with attaining the numeric target and therefore the water quality standards. Additionally, as discussed in **Section 3**, modeling indicates the Lake Discharge will likely improve TP and chlorophyll-a concentrations in the Lake. The Lake Discharge would therefore be able meet one of the key requirements for attaining a permit by being able to "*comply with*" applicable water quality standards associated with the TMDL. (40 C.F.R. § 122.44(d)(1)(vii)(A)).

However, as noted in the Nutrient TMDL Background discussion, even though the discharge quality is projected to be below the TP numeric target, the Nutrient TMDL did not include a WLA for the Lake Discharge. As a result, to be consistent with the Nutrient TMDL assumptions, the Lake Discharge in essence needs to have a zero TP WLA during dry hydrologic conditions. Including requirements in the NPDES permit to implement

actions that will offset the TP loads entering the Lake would be equivalent to assigning a zero WLA. The combination of WQBELs calculated based on the TMDL numeric target and offsets would be consistent with the Nutrient TMDL assumptions and support attainment of the water quality standards. While the Nutrient TMDL WLA only applies during dry hydrologic conditions, the Agency Team proposes to conduct TP offsets during all hydrologic conditions to simplify implementation and tracking and to provide a more conservative approach.

The remainder of this section discusses the proposed offsets and how they align with the structure outlined above.

4.3 Proposed TP Offset Program

As part of the Replenish Big Bear Program, the Agency Team is proposing to offset the TP loads introduced by the Lake Discharge to attain a net zero TP loading to be consistent with the Nutrient TMDL WLA assumptions and to apply these offsets during all hydrologic conditions. The proposed TP offset strategy is to proactively apply alum every three years to offset the estimated TP load for the upcoming three years (estimated up to 200 lbs/yr or 600 lbs TP). In the event of extreme runoff (defined here as exceeding about 25,000 AFY), which has the potential to bury the reactive alum cap on the sediments and reduce its effectiveness, an alum treatment will be conducted that following spring-summer and the triennial treatment schedule will be reset. This approach will provide reliable TP load offsets.

In general, alum is a compound used to bind to reactive available phosphorus in the water column, flocculate particulate phosphorus, and reduce internal phosphorus loading from lakebed sediments. After the alum binds to the phosphorus it becomes aluminum phosphate, an inert crystalline compound which renders the phosphorus unavailable to plants and algae as a nutrient. Algae and plants require nitrogen and phosphorus to grow. Since the lake is phosphorus limited, removing phosphorus helps reduce the potential for algae blooms in the summer and slows the growth of aquatic plants in the lake. After the alum sinks to the bottom of the lake, it settles and creates a reactive floc layer which can cap the lakebed sediments and prevent the phosphorus therein from mobilizing out of the sediment and into the water column. Alum treatments often last up to ten years before sorption capacity is exhausted and reapplication is needed.

In 2004, BBMWD, in collaboration with the State Water Board, applied 700,850 gallons of alum across 1,500 surface acres to sequester phosphorus and aid in controlling chlorophyll-a. The estimated TP sequestered from this project was 17,170 lbs per the TMDL annual reports. The application had a significant immediate impact on sequestering phosphorus.

In 2015, BBMWD, in collaboration with the Nutrient TMDL stakeholders, applied 574,832 gallons of alum over 20 days in May and June of that year. Phosphorous concentrations in the lake were elevated at the time due to years of drought and external and internal nutrient loading. The treatment was limited to 420 acres at the western end of the lake where the highest concentrations of phosphorus were found. The estimated TP sequestered from this project was 14,100 lbs per the TMDL annual reports.

As done in 2015, the initial alum application for the TP Offset Program will target the phosphorus-rich organic sediments in the western end of the Lake, where highest dissolved (hypolimnetic) phosphorus and highest sediment phosphorus flux rates are found. Since the objective of these alum applications is to offset a very modest TP loading from the Lake Discharge, rather than substantially reduce internal TP loading and favorably alter the overall TP budget of the lake (which is on the order of 26,000 lbs/yr), it should be noted that marked quantifiable improvements in water quality would not be expected solely as a result of the offset program, especially given the natural variability in hydrology and water quality in the lake. It is anticipated that BBMWD, as the Lake manager, will lead the implementation of the TP Offset Program on behalf of the partner agencies.

4.4 Demonstration that Offsets are Aligned with TMDL Requirements

To evaluate the potential impact of the offsets, further modeling was conducted to evaluate predicted water quality with the TP offset for comparison with the baseline condition and project scenarios without the TP offset. Given the complexity of nutrient budgets of lakes and equivalence of a given form of nutrient irrespective of its particular origin, TP offset was modeled as equivalent to a Lake Discharge with a concentration of 0 mg/L TP. This is an approximation that holds when considering the whole-lake nutrient budget but is nonetheless a simplification; depending upon details of offset, hydrodynamic considerations and other factors, some modest lateral gradients in water quality may result.

Zeroing out the load of TP in the Lake Discharge yielded further reductions in chlorophyll-a. Larger total inflow volumes with reduced summer flows and no net TP loading were predicted to yield growing season average chlorophyll-a concentrations as low as 9.5 - 10.2 µg/L, significantly below predicted baseline and TMDL concentrations (**Table 8**).

Table 8. Long-Term Average Predicted Concentrations of TP and Chlorophyll-a in Big Bear Lake with TP Offset (TP Expressed as Annual Average Concentrations; Chlorophyll-a Shown as Growing Season Average Concentrations)

Operational Scenario (all at 50th % hydrology)	TP (mg/L)	Chlorophyll-a (µg/L)
TMDL target	***0.0350***	***14.0***
Baseline	0.0477	14.1
1920 AFY (2021 Lake Model Analysis)	0.0433	14.0
2210 AFY (99% recovery)	0.0423	13.1
2009 AFY (90% recovery)	0.0434	12.9
2210 AFY + offset TP	0.0399	10.2
2009 AFY + offset TP	0.0409	9.5

While it is important to recognize the uncertainty in model predictions, it is nonetheless noteworthy that the simulation of the TP offset yielded average chlorophyll-a concentrations significantly below baseline and Nutrient TMDL target values. Predicted long-term average TP concentrations remained above the Nutrient TMDL target but were nonetheless meaningfully lower than the predicted baseline level (**Table 8**). Inter-annual differences in water quality are also expected to persist. Cumulative distribution functions (CDFs) highlight the predicted wide range in annual and growing season average concentrations (**Figure 3**). The Lake Discharge resulted in lower annual average TP and growing season average chlorophyll-a concentrations than Baseline under all conditions (**Figure 3**).

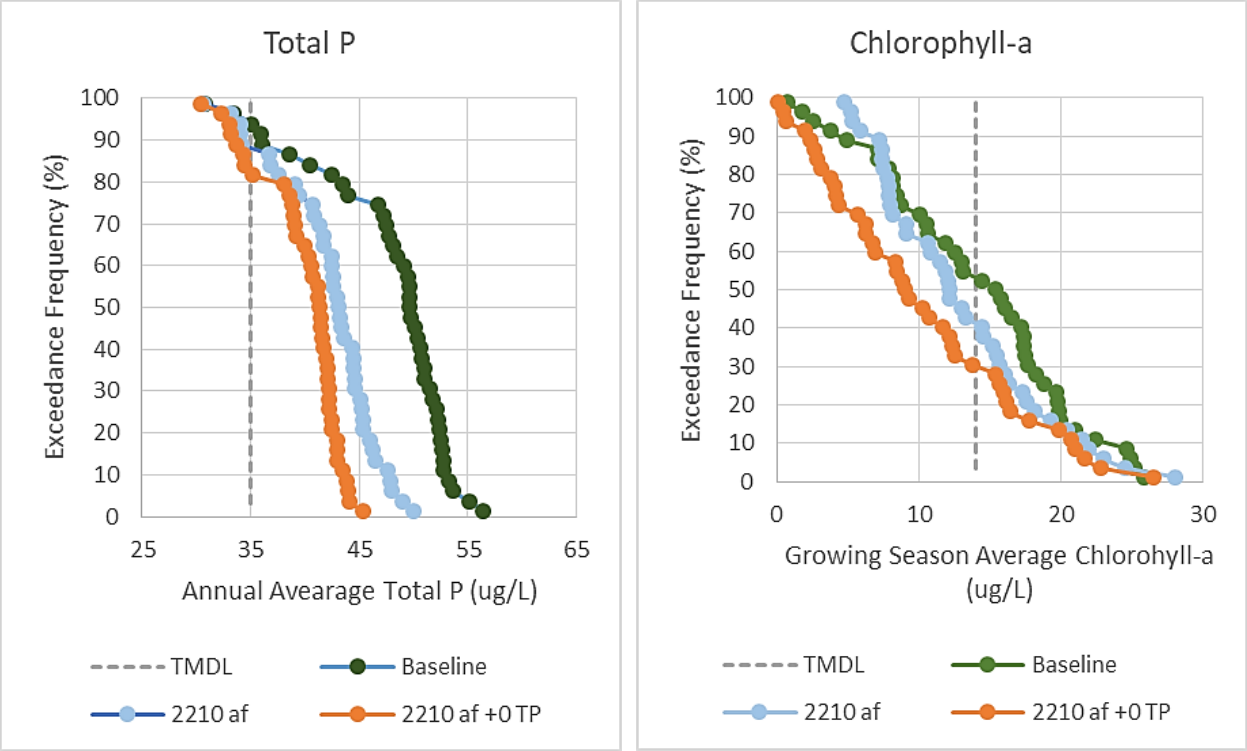

Figure 3. Cumulative Distribution Functions for Predicted Annual TP and Growing Season Average Chlorophyll-a Concentrations for Baseline Condition and with 2,210 AFY Lake Discharge with and without TP Offset.

The model predicted Baseline exceedance frequencies are similar to the observed annual exceedance frequencies based on the TMDL Annual Reports both TP and chlorophyll-a (**Table 9**)

Table 9. Predicted frequency of exceeding TMDL target under baseline conditions and different RBB inflow and TP offset scenarios (annual average or growing season average basis). Observed annual exceedance frequencies for 2009-19 period from TMDL Annual Reports shown in parentheses under Baseline.

Variable	Baseline	2210 AF	2210 AF + 0 TP
TP	94 % (100%)	87 %	82 %
Chlorophyll-a	53 % (55%)	41 %	31 %

As discussed above, the Lake Discharge contributes a minimal amount of loading compared to the other sources described in the Nutrient TMDL. Therefore, the Lake Discharge in and of itself does not need to result in attainment of the water quality standards. Rather, the Lake Discharge, in combination with the other efforts required by the Nutrient TMDL should result in attainment of the water quality standards. The 2021 Lake Model Analysis demonstrates that the Lake Discharge will likely contribute to more

frequent attainment of the Nutrient TMDL numeric targets and associated water quality standards, especially when combined with the offset program and actions taken by the TMDL responsible parties to attain the Nutrient TMDL requirements. Additionally, the Lake Discharge will increase Lake levels, which will contribute to protection of other beneficial uses and reduce the amount of time critical hydrologic conditions occur in the Lake.

5 Conclusion

In conclusion, permitting the Lake Discharge in the context of the existing Nutrient TMDL can be accomplished by:

1) Establishing TP WQBELs that are consistent with the Nutrient TMDL assumptions; and
2) Making permit findings that the WQBELs are derived from and comply with water quality standards.

The TP WQBELs that are based on the Nutrient TMDL numeric targets and include requirements to implement the offset strategies outlined in this TM would be consistent with the Nutrient TMDL numeric targets and the assumptions of the Nutrient TMDL allocations. Additionally, because the Nutrient TMDL numeric targets were established to meet water quality standards, WQBELs based on the Nutrient TMDL numeric targets would be derived from and comply with water quality standards. Finally, the 2021 Lake Model Analysis and subsequent additional model analysis results can be used to demonstrate that the Lake Discharge will provide benefits to beneficial uses and likely help improve water quality in the Lake.

In the future, if the Nutrient TMDL is revised, allocations can be assigned to the Lake Discharge. Then permit conditions could be revised (e.g., removing the offset framework), if appropriate to reflect the TMDL allocations.

SUBJECT: LEGAL AUTHORITY FOR OFFSETS, POLLUTANT TRADING, AND MARKET PROGRAMS TO SUPPLEMENT WATER QUALITY REGULATION IN CALIFORNIA'S IMPAIRED WATERS

I. Introduction

This memorandum has been prepared to outline the existing legal authority to employ offsets, pollutant trading, and other market programs to supplement water quality regulation in impaired waters. While there is no fixed definition of these terms, "offsets" generally refer to unilateral abatement efforts by a discharger to remove a certain amount of pollutant discharge from existing sources to compensate for the discharger's own discharge. "Pollutant trading" generally refers to an exchange of either permitted discharge levels or required abatement levels between two or more dischargers, either in a formal "commodities" market or banking system, or a less structured exchange.

In sum, the extent to which such mechanisms may be employed varies greatly depending upon whether a TMDL has been adopted for the impaired water, although they may be permissible in either context. The analysis in this memorandum is equally applicable for any market-type mechanism, be it offsets, pollutant trading, or another analogous system that would authorize one discharger to perform (or to encourage another to perform) additional abatement or restoration in lieu of meeting an otherwise applicable or more stringent discharge limitation or prohibition.

This memorandum should not be construed as delineating the universe of possible market-scenarios that may be legal in given circumstances. Each such system must be evaluated in the context of its own circumstance. However, this document is intended to discuss some of the legal issues that will arise in considering such systems. These include at least the anti-

backsliding rule, and the extent to which the regulations authorize new or renewed permits to be issued for discharges into impaired waters.

In considering any of these approaches, Regional Water Quality Control Boards (Regional Boards) should be cognizant of the state's legal obligation to adopt and implement approximately 1400 TMDLs. Accordingly, any market system should only be contemplated under circumstances that will promote (and not forestall) TMDL development or attainment of water quality standards.

II. Irrespective of whether a TMDL exists, federal law requires each point source to be subject to applicable technology based effluent limitations (TBELs) as a floor.

Section 402(b) of the CWA requires that all NPDES permits issued by California contain applicable TBELs. (33 U.S.C. § 1342(b)(1)(A). See also 33 U.S.C. §§ 1311, 1313(e)(3)(A).) Effluent limitations based upon the best available technology are the floor and the minimum that must be required of any NPDES permitted discharge. Thus, no market system can be adopted that would afford relief from TBELs in NPDES permits, for either new or existing sources.

III. When a TMDL is in place, the Clean Water Act (CWA) and California law give wide latitude to develop creative means of achieving compliance with water quality standards (WQS), subject to certain limitations.

A. The water quality based effluent limitations (WQBELs) applicable to new or existing point sources can be adjusted in compliance with a TMDL.

NPDES permits must also incorporate "any requirements in addition to or more stringent than [TBELs] necessary to . . . [a]chieve water quality standards." (44 C.F.R. § 122.44(d)(1).) See also 33 USC §§ 1342(b), 1311(b)(1)(C).) Unlike TBELs, these water quality based effluent limitations (WQBELs) can be adjusted in contemplation of a TMDL. While the CWA's anti-backsliding provisions would ordinarily prohibit the state from permitting a less stringent effluent limitation, section 402(o) contains an express exception applicable when a TMDL is in place. (33 U.S.C. § 1342(o).) Specifically, if the water is impaired, existing WQBELs may be relaxed if "the cumulative effect of all such revised effluent limitations based on such [TMDL] or waste load allocation will assure attainment of such [WQS]." (33 U.S.C. § 1313(d)(4)(A).)

Federal regulations bolster these provisions. Under the regulations, WQBELs must be "consistent with the assumptions and requirements of any available wasteload allocation . . . ." (40 C.F.R. § 122.44(d)(1)(vii)(B).) The regulations do not require WQBELs to be "equivalent to" available waste load allocations. Accordingly, so long as the cumulative effect of all WQBELs assures attainment of WQS, hence the assumptions of the TMDL, WQBELs can be adjusted based upon whatever mechanisms the state determines is appropriate.

This regulatory structure is equally applicable to new sources. A WQBEL that otherwise would be applicable to a new source can also be adjusted based upon a TMDL, whether through the use of offsets or other appropriate measures, that insure attainment of WQS. The CWA's anti-backsliding provisions do not apply to new dischargers.

To avoid a claim that a given NPDES permit is inconsistent with a TMDL, if any such mechanisms are contemplated, it would be appropriate to incorporate pertinent details of the market-based provisions into the TMDL implementation plan. If sufficient details of potential market approaches are not known at the time the implementation plan is adopted, alternatively, Regional Boards can retain flexibility in translating WLAs into effluent limitations by articulating a provision similar to the following in the implementation plan:

> "While individual WQBELs shall be consistent with the assumptions and requirements of the available WLAs, LAs, and the TMDL, individual WQBELs need not be equivalent to corresponding allocations so long as the cumulative effect of all WQBELs assures attainment of WQS as quantified by the TMDL. (33 U.S.C. § 1313(d)(4)(A); 40 C.F.R. § 122.44(d)(1)(vii)(B).)"

Although failure to include the above language would not necessarily preclude subsequent flexibility in implementation, the better practice, given the public-participation requirements, would be to minimize surprises by disclosing up front that alternative attainment mechanisms may be employed.

Nonpoint Source Discharges

TMDLs must identify and grant allocations to all sources of pollution, including load allocations to nonpoint sources. The TMDLs therefore may disclose nonpoint sources as likely candidates to be offsets for point sources in addition to or apart from other point-source abatement. In appropriate circumstances, i.e., where load reductions can be calculated and enforceable, offsets may also be applied for the benefit of nonpoint sources as well as point sources.

Since the CWA does not directly regulate nonpoint sources, such discharges are subject to applicable limitations set forth under state law. California's primary mechanism to protect water quality for non-NPDES discharges (be they nonpoint source, or point source discharges to non-navigable waters) is through issuance of waste discharge requirements (WDRs) under Water Code section 13263. The extent to which offsets can be used in this context is derived from the state's authority to issue WDRs generally. Specifically:

> The requirements [for waste discharge] shall implement any relevant water quality control plans that have been adopted, and shall take into consideration the beneficial uses to be protected, the water quality objectives reasonably required for that purpose, other waste discharges, the need to prevent nuisance, and the

> provisions of Section 13241 [dictating matter to be considered in establishing water quality objectives]. (Water Code § 13263(a).)

Section 13241 in turn requires consideration of, among other things, "[w]ater quality conditions that could reasonably be achieved through the coordinated control of all factors which affect water quality in the area." (Water Code § 13241(c).)

Since the basin plans protect beneficial uses and articulate water quality objectives, any WDRs issued must be protective of those uses and meet the objectives. Notably, the Regional Boards are authorized (1) to not utilize the full waste assimilation capacities of the receiving waters and (2) to utilize time schedules if they determine them appropriate in their discretion. (Water Code § 13263(b) and (c).) These authorizations may be further elucidated upon or restricted in a region's applicable basin plan. Moreover, given Section 13241(c) of the Water Code, it would be appropriate in establishing WDRs for a particular discharger to consider the affect that other pollution control measures in the area could have on the water body. So long as such other measures are implemented, and the cumulative effect of such measures and the discharge meet water quality objectives, the level of abatement required in the WDRs could be adjusted accordingly.

Traditionally, California's nonpoint sources have been regulated through general WDRs or general waivers of WDRs. Waivers of WDRs are subject to the restriction that the waiver not be "against the public interest." (Water Code § 13269(a).) In its Nonpoint Source Management Plan, the state has committed to controlling nonpoint source pollution through a three-tiered approach, rather than though immediate issuance of individual WDRs. First, it will encourage self-determined pollution abatement measures. Second, it will employ regulatory incentives to achieve the desired results. Third, if the other tiers are unsuccessful, the state will issue WDRs to nonpoint source dischargers or use other direct regulatory mechanisms. (Nonpoint Source Program Strategy and Implementation Plan, 1998-2013 (PROSIP) pp. 54-60.)

The second tier is exceptionally amenable to use of conditional waivers of WDRs. Participation in an offset program that is part of a water quality attainment strategy (such as a TMDL) could be a proper condition upon which WDRs could be waived. Since the offset is part of a water quality attainment strategy, it would presumably not be against the public interest. Notably, the authority to waive WDRs is qualified by the provision that the Regional Boards must "require compliance with the conditions pursuant to which waivers are granted under this section." (Water Code § 13269(e).) It would also be permissible to incorporate an offset as a requirement in WDRs themselves, for the same purposes as set forth above.

IV. In the absence of a TMDL, offsets must be consistent with the regulations that require all discharge permits to implement WQS.

A degree of uncertainty exists about the U.S. Environmental Protection Agency's (EPA) position on whether offsets are appropriate in the absence of a TMDL. EPA proposed an offset program that was published in the Federal Register on August 23, 1999. That program would have allowed new discharges in the absence of a TMDL, provided the new discharge and offset together demonstrated "reasonable further progress" toward attainment, and therefore did not violate the antidegradation rules. At least a 1.5 to 1 offset ratio was determined to generally constitute reasonable further progress. On July 13, 2000, however, EPA published its abandonment of the rules that would have implemented the program. Notably, the program was not abandoned for illegality, but because EPA determined its offset requirement, as proposed, was not the best mechanism to achieve progress in impaired waters in the absence of a TMDL, especially given the existing regulations set forth at 40 Code of Federal Regulations (C.F.R.) sections 122.4(d)(1)(vii), and 122.4(i).

EPA's findings were directed to the utility of a nationwide fixed offset policy, and do not necessarily imply that EPA is opposed to offsets in any given or all circumstances. In fact, there are several prominent indications to the contrary. (See e.g., Draft Framework for Watershed-Based Trading, U.S. EPA Office of Water, EPA 800-R-96-001 (May, 1996); EPA Region 9 Draft Guidance for Permitting Discharges into Impaired Waterbodies in Absence of a TMDL (5/9/00).[1]) Given that no statutes or regulations directly address market-approaches to water quality regulation, any such programs must be examined within the confines of the existing regulatory structure.

<u>New Sources</u>: An NPDES permit cannot be issued to a new source if it would "cause or contribute" to a violation of WQS. In appropriate circumstances, however, a new discharge, coupled with an offset, might be deemed to not "cause or contribute" if the new discharge is not merely a substitute contributing source of pollution for the offset.

The NPDES regulations prohibit new discharges that would contribute to a violation of WQS:

> No permit may be issued … [¶ to] a new source or a new discharger, if the discharge from its construction or operation will cause or contribute to the violation of water quality standards. (40 C.F.R. § 122.4(i).)[2]

[1] Note: Since these are draft documents, they should not be relied upon as reliable authority for any position. Their inclusion here is exclusively for illustrative purposes only.

[2] Notably, this regulation is also qualified when a TMDL is in place, and requires the discharger to undertake a load assessment to demonstrate that additional assimilative capacity exists to allow the discharge. (40 C.F.R. § 122.4(i).)

While this language could be interpreted as prohibiting all new discharges into impaired waters without a TMDL, neither the U.S. Supreme Court nor EPA have adopted that position. (See *Arkansas v. Oklahoma* (1992) 503 U.S. 91, 107-108, but see *In The Matter of: Mayaguez Regional Sewage Treatment Plant Puerto Rico Aqueduct and Sewer Authority* (1993) 4 E.A.D. 772, fn. 21 [limiting *Arkansas* to its facts]. See also 65 Fed.Reg. 23640 col. 3.)[3] In fact, it can properly be argued that a new discharge does not "cause or contribute" if coupled with an appropriate offset.

Determining whether a new discharge, coupled with an offset, will "cause or contribute to" the violation of WQS involves a degree of factual analysis, and a degree of interpretation. If a new discharger, for instance, were to propose a one-to-one mass offset from other dischargers (be they existing point or nonpoint sources) for the discharger's increased waste load, the discharge would involve merely the substitution of one contributing source of impairment for another. A new contributing source that substitutes for an existing contributing source is still a contributing source. As such, a one-for-one offset scenario would probably be prohibited by the federal regulations.

Likewise, offsets in a venue remote to the proposed discharge would not offset the impairment-contribution from a new discharge, as the offset program would not yield benefits to the relevant water quality limited segment. Such a new discharge would merely be an additional contributing source of impairment. Again, this would appear to be prohibited by the same authorities.

On the other hand, if a discharger performs offsets greater than one-to-one, in a venue relevant to the new discharge, it may well properly be deemed to not "cause or contribute" to the impairment. In such circumstances, the net result is actually to improve water quality.

Given the regulatory prohibition against contributing to excursions above objectives, in the absence of a TMDL benchmark, the safest offsets would involve projects whose relevance to attainment of WQS should be apparent. Accordingly, if a new discharger were to instigate, for example, a legacy-abatement program, especially if such a program was probably necessary to attainment but would not readily be accomplished were it not for the efforts of the new discharger, a good argument would be apparent that the offset is not merely a substitute for an existing contributing source. If the legacy abatement efforts created significant quantifiable mass abatement above and beyond the new discharge, the cumulative effect of the discharge and offset can properly be viewed as improving water quality. Likewise, if a new source cannot meet concentration-based effluent limitations, an offset that achieved a sufficient reduction in background levels might fall within this category as it could provide room for dilution that might not otherwise be available.

[3] Though not relevant to the subject of this memorandum, an obvious flaw in the no-discharge position is the fact that discharges meeting criteria end-of-pipe necessarily do not contribute to excursions above criteria.

The variable in the above analysis, however, is the lack of knowledge of the relevance of the offset to the water's impaired status. Without such knowledge, it may often be difficult to determine whether the improvement from the offset will be sufficient to defensibly reach the conclusion that the discharge is not merely a substitute cause of impairment. Any offset program in the absence of a TMDL will therefore be subject to significant scrutiny, and its defensibility in the absence of knowledge of the TMDL benchmark values, will be fact-specific, and will include an evaluation of numerous factors. These will no doubt include at least an evaluation of the substantiality of the offset achieved in exchange for the discharge (offset-ratio), as well the level of certainty that the offset program will abate a sum-certain of contributing pollutants. The inquiry may properly also include a consideration of the likelihood that the source to be offset would or could be abated through other means (the less likely the source is to be abated through other means, the more compelling the need to find alternative incentives to abate it) and whether the offset generates a permanent or temporal abatement. In any event, where a definitive improvement in water quality can be shown, such offsets ought to be encouraged.

The key legal point is that since federal law prohibits new discharges that cause or contribute to violations of water quality standards, to be defensible, any offset program must do more than substitute one contributing source for another. The program should significantly drive the watershed toward attainment or otherwise toward development of a TMDL. The key practical point is that an offset program in the absence of a TMDL should be chosen carefully to maximize the chances that a reviewing court (one that may be ideologically opposed to offsets) will find the facts compelling enough to sustain despite any skepticism.

Legacy-abatement and watershed-restoration efforts, for example, seem particularly amenable to pre-TMDL circumstances for the reasons set forth above. Such efforts may yield permanent benefits to the watershed in exchange for a temporal discharge. These offsets do not merely substitute one source for another, but create assimilative capacity through improvements to the overall environmental health of the watershed. In many cases, such efforts may ultimately need to be undertaken as part of a TMDL implementation plan in any event. Accordingly, rather than forestalling TMDL development and implementation, offsets of this nature may promote the state's performance of its TMDL obligations, and may do so in advance of formal TMDL implementation.

<u>Existing Sources</u>: Whether offsets can be used to allow relief from an otherwise applicable WQBEL, without a TMDL, depends upon whether the anti-backsliding rules apply, and if not, whether the discharge is protective of WQS.

1. Anti-backsliding

A key distinction between new and existing sources is the anti-backsliding rule. The anti-backsliding rule provides that, unless certain exceptions are met:

> [A] permit may not be renewed, reissued, or modified . . . subsequent to the original issuance of such permit, to contain effluent limitations which are less stringent than the comparable effluent limitations in the previous permit except in compliance with section 1313(d)(4) of this title. (33 U.S.C. § 1342(o).)

Since an offset program by definition provides a discharger with an avenue to obtain flexibility in lieu of the application of an otherwise stringent effluent limitation, the extent to which the anti-backsliding rule applies could have significant consequences in terms of the permissibility of offsets. However, there are many circumstances in which the anti-backsliding rule does not apply.[4] The most notable of these is the limitation that the rule only applies to the "comparable effluent limitations in the previous permit." (*Id.*)

In SWRCB Order WQ 2001-06 (The Tosco Order), the State Water Resources Control Board (State Board) addressed the question of whether effluent limitations in interim permits—permits reissued prior to the adoption of a TMDL—are "comparable effluent limitations" to those in the previous permit. The Tosco Order held that the discharger's interim performance-based effluent limitation, in a compliance schedule, was not a comparable effluent limitation to that set forth in its final limit from the previous permit. The State Board reached this result for two reasons. First, the interim limit at issue was a performance-based effluent limitation, which was issued pursuant to a compliance schedule that was authorized under the applicable Regional Water Quality Control Plan. Such interim limits, the State Board held, are not designed to attain water quality, but to preserve the status quo during the term of the compliance schedule. Furthermore, if the anti-backsliding rule were deemed to apply to such limits, it would effectively prohibit compliance schedules. (Order WQ 2001-06, pp. 51-52.) Since the previously permitted final effluent limitation was a WQBEL, and the interim limitation was performance based, the two effluent limitations were not "comparable" as they were not derived with the same considerations in mind. Instead, the "comparable limit," the State Board held, would be the alternative final (water quality based) limit, not the interim (performance based) limit. Since the two effluent limits were not comparable, the fact that the interim limit was less stringent than the previous final effluent limit did not violate the anti-backsliding rule.[5]

---

[4] 33 U.S.C. section 1342(o)(2) contains five exceptions to the anti-backsliding rule, that may render it inapplicable to a given discharge. While these are not discussed separately in this memorandum, if any of these exceptions apply, the analysis that follows would also apply.

[5] This theory would apply whenever a compliance schedule may authorize an interim discharge in excess of limits established in a prior permit. Other authorities provide for compliance schedules in appropriate, instances, most notably, EPA's California Toxics Rule (CTR) and the state's policy that implements it, authorizes a compliance schedule as to CTR criteria pollutants when a discharger shows that immediate compliance with criteria is infeasible, and the discharger had committed to support and expedite development of a TMDL. (Policy for Implementation of Toxics Standards for Inland Surface Waters, Enclosed Bays, and Estuaries of California § 2.1.1 (2000).)

This finding has been challenged by a writ petition to the superior court. In that proceeding, the petitioner contends the term "comparable limit" refers to the permitted levels of pollutant discharge, not to the way the levels were derived. If the petitioners prevail, there will be far less permitting flexibility for interim permitting of existing facilities. Assuming the State Board's finding is affirmed, however, those regions whose applicable water quality control plans authorize compliance schedules may, if they choose, adopt offset requirements in conjunction with an interim permittee's compliance schedule. In cases where the interim limit is deemed comparable to the previous limit (be it on the basis of the Tosco reasoning or a subsequent judicial interpretation), section 402(o) may be an impediment to relaxing the effluent limitation to accommodate an offset in the absence of a TMDL.

2. Potential situations where the anti-backsliding rule may not apply

a. Bubbling of NPDES permitted sources

In the 1970s, the U.S. EPA endorsed permit "bubbling" for stationary sources subject to the federal Clean Air Act. Bubbling entailed treating multiple sources as though they were a single source, with an aggregate emissions limit. Since there was a total limit based on the bubble output, the individual sources within a given bubble could allocate the emissions amongst themselves, provided the sum of all emissions did not exceed the bubble limitation. This concept is similar to the mechanisms employed by the Grassland Bypass Project, which controls selenium in nonpoint source agricultural discharges to levels sufficiently protective that the San Luis Drain could be reopened. The San Luis Drain is treated as one outfall for purposes of the Project. As long as the Drain output attains standards, the dischargers may determine for themselves who may discharge what amount.

As noted, anti-backsliding applies only to "comparable effluent limitations in the previous permit." Nothing in the Clean Water Act prohibits issuing a single NPDES permit that regulates several sources. Certainly the limitations set forth in such a super-permit are not "comparable" to prior limitations imposed on individual sources now subject to the super-permit. At most all that could be said is that the super-permit is comparable to the totality of all the super-permittees' individual permits. Thus while such a super-permit could not properly expand the universe of what was individually permissible by the collective, individuals should not be deemed to backslide if the total output of the bubble does not exceed the cumulative total of the individuals. Of course, when using any bubbling mechanism, care must be taken to insure criteria are attained at all points within the bubble. A market system cannot authorize participants to discharge in a manner that would cause or contribute to excursions above criteria. (40 C.F.R. § 122.4(i); 40 C.F.R. § 122.44(d)(1)(vii)(A).)

b. Mini- or Partial TMDL

Although a TMDL may not have been created, often the major sources of impairment are well known. Frequently, abatement of these sources may be regarded as essential to any TMDL implementation plan even though such a plan is not yet being developed. Under such circumstances, it may be possible to create a mini- or partial TMDL that assigns preliminary LAs or WLAs to dischargers who undertake or participate in abatement of these sources in advance of the final TMDL. Since these LAs or WLAs would be assigned in exchange for abatement necessary to the success of the ultimate TMDL, they are plainly either "based on a [TMDL] or other waste load allocation." (33 USC § 1313(d)(4)(A).) The CWA, which thus contemplates that WLAs can be created apart from a final TMDL, supports this interpretation. Note that, as above, even with a TMDL, local excursions above criteria must be prevented.

3. Similar to new permits, existing permits must insure compliance with WQS.

Irrespective of anti-backsliding, interim permits must protect applicable WQS. 40 C.F.R. section 122.44(d) requires that NPDES permits contain any more stringent requirements necessary to achieve water quality standards. Specifically, when WQBELs are developed, the permitting authority "shall ensure that:"

> The level of water quality to be achieved by limits on point sources established under this paragraph *is derived from, and complies with all applicable water quality standards*. (40 C.F.R. § 122.44(d)(1)(vii)(A) (emphasis added).)

Moreover, permits shall incorporate "any more stringent limitation, including those necessary to meet water quality standards" or those "required to implement any applicable water quality standard established pursuant to this chapter." (33 U.S.C. § 1311(b)(1)(C). See also 40 C.F.R. § 122.44(d)(5).)

The extent to which the above language authorizes or prohibits offsets in the absence of a TMDL is not clear. While it appears to be somewhat less proscriptive than the companion "cause or contribute" requirement applicable to new sources (see 40 C.F.R. § 122.4(i), supra), in practice they appear to have the same effect. (See e.g. 40 C.F.R. § 122.44(d)(1)(i).) Accordingly, the analysis set forth in section IV.A., supra, would be equally applicable here.

Variances

Similar to compliance schedules, which grant extensions of time to comply with criteria, the federal regulations authorize the use of variances in the State's discretion, subject to EPA's approval. (40 CFR § 131.13.) Where variances are authorized, Regional Boards may grant such variances in consideration of, or condition them upon, the performance of an appropriate offset which helps guarantee that protection of beneficial uses will not be compromised or that the

public interest will be served. (See Water Code § 13269.) Variances are authorized in certain circumstances, e.g., in section III.I of the California Ocean Plan (2000), as well as in the Policy for Implementation of Toxics Standards for Inland Surface Waters, Enclosed Bays, and Estuaries of California at section 5.3, for categorical and case-by-case exceptions to CTR criteria for resource and pest management, and for drinking water. Individual Regional Water Quality Control Plans may also authorize variances for conventional pollutants as well. Notably, Water Quality Order No. 2001-12-DWQ, the recent statewide general NPDES permit for the discharge of aquatic pesticides, grants such a categorical exception.

V. Conclusion

The use of offsets, pollutant trading, or other market-based mechanisms to supplement water quality regulation in impaired waters is clearly appropriate when implemented in the context of a TMDL, in which case, substantial flexibility exists to achieve WQS. For impaired waters for which no TMDL has yet been created, the anti-backsliding rules must be considered. However, when considered in the context of regulating multiple sources with a single NPDES permit (bubbling), staged TMDL efforts, or other scenarios, the anti-backsliding rules may not be a restraint on the use of market-based regulation.

For new and existing sources, the federal regulations provide that new discharges may not "cause or contribute" to violations of WQS, and that existing discharges must be "derived from and comply with" all applicable WQS. However, significant legacy abatement programs or another large-scale offsets, may well meet regulatory scrutiny depending upon fact-specific circumstances that lead the Regional Board to conclude that, even in the absence of a TMDL, the offset coupled with the discharge, creates a watershed-based improvement of a magnitude that justifies a finding that the discharge does not contribute to impairment, and is consistent with WQS. As noted above, even in the absence of a final TMDL there may nonetheless be significant flexibility in certain circumstances, which must be evaluated within the context of the facts presented.

In any event, given the scope of California's obligations under CWA section 303(d), specifically the roughly 1400 TMDLs that must be adopted, as a practical matter, care should be taken that creative mechanisms, in advance of a TMDL, should be promotive of TMDL development or attainment of criteria generally.

Should you have any questions about this memorandum, please contact me at 341-5150, or Staff Counsel Michael Levy at 341-5193 or mlevy@exec.swrcb.ca.gov.

EXECUTIVE SUMMARY

Project Description

The Big Bear Area Regional Wastewater Agency (BBARWA) operates an existing regional wastewater treatment plant (WWTP) and related facilities in the Big Bear Valley (Valley). BBARWA has partnered with Big Bear City Community Service District (BBCCSD), Big Bear Lake Department of Water and Power (BBLDWP), Big Bear Municipal Water District (BBMWD), and Bear Valley Basin Groundwater Sustainability Agency (BVBGSA), collectively known as the Agency Team, to develop the Replenish Big Bear Program. The Replenish Big Bear Program is intended to help protect the Valley and the Santa Ana Watershed from the impacts of drought and variable precipitation by recovering a water resource currently discharged outside of the watershed. The program is comprised of several elements; the first project includes treatment upgrades at the BBARWA WWTP to produce disinfected, advanced treated effluent by providing tertiary filtration, reverse osmosis (RO) treatment, and ultraviolet (UV) disinfection for 100% of the water proposed to be discharged to Stanfield Marsh Wildlife and Waterfowl Preserve (Stanfield Marsh), a tributary of Big Bear Lake (Lake) and a separate discharge to Shay Pond, a tributary of Shay Creek. These discharges are referred to as the "Lake discharge" and the "Shay Pond discharge" and the approximate discharge locations are shown in **Figure ES-1**.

The new BBARWA WWTP facilities will be designed for a treatment capacity of 2.2 million gallons per day (MGD). By 2040, accounting for expected growth, it is estimated that the WWTP could produce 2,210 acre-feet per year (AFY) of advanced treated effluent, assuming a 99% total recovery rate could be achieved (90% RO recovery and 90% recovery of brine through brine minimization). Up to 80 AFY of the disinfected, advanced treated effluent will be sent to Shay Pond discharge, and any remaining disinfected, advanced treated effluent will be sent to the Lake discharge. All remaining flows in excess of the new treatment train's 2.2 MGD capacity will continue to be treated to undisinfected secondary standards and conveyed to BBARWA's existing Lucerne Valley site, which is regulated by the Colorado River Basin Regional Water Quality Control Board.

As described in the Technical Memorandum (Attachment B of the ROWD package) titled *Approach to Address Big Bear Lake Nutrient Total Maximum Daily Load in the NPDES Permit for Big Bear Area Regional Wastewater Agency (WSC & LWA, 2022)*, the Agency Team proposes to implement a total phosphorus (TP) Offset Program for the Lake discharge to attain net zero TP loads to the Lake to be consistent with the assumptions of the Big Bear Lake Nutrient Total Maximum

Daily Load (Nutrient TMDL) for Dry Hydrologic Conditions. While a portion of the disinfected, advanced treated effluent is planned for discharge to Shay Pond, the maximum anticipated Lake discharge of 2,210 AFY, coupled with the TP Offset Program in the Lake, is the basis of the antidegradation analysis for the Lake discharge. Modeling analysis has also been conducted to evaluate a range of additional scenarios; these results are presented herein to provide additional information.

The proposed Lake discharge will be physically discharged at the east end of Stanfield Marsh, then flow through the Marsh into the Lake through a set of culverts under Stanfield Cutoff. Due to prolonged drought conditions, Stanfield Marsh has been mostly dry since 2015. Therefore, current ambient water quality data is not available. Additionally, the water quality objectives (WQOs) specified for the Lake in the Water Quality Control Plan for the Santa Ana River Basin (Basin Plan) are more stringent than those for Stanfield Marsh. Therefore, this antidegradation analysis focuses on the impacts to water quality in the Lake.

This antidegradation analysis provides the Santa Ana Regional Water Quality Control Board (Regional Water Board) with the information needed to determine whether the proposed Lake discharge and Shay Pond discharge are consistent with the State of California (State) and federal antidegradation policies.

Note that the Replenish Big Bear Program also includes subsequent uses of Lake water for purposes such as 1) landscape irrigation, construction uses, and snowmaking at the golf course and ski resort and 2) direct groundwater recharge in Sand Canyon. It is anticipated that these uses will be regulated separately and are not discussed in this antidegradation report. Coordination with the California State Water Resources Control Board Division of Drinking Water (DDW) is underway to regulate these recycled water uses.

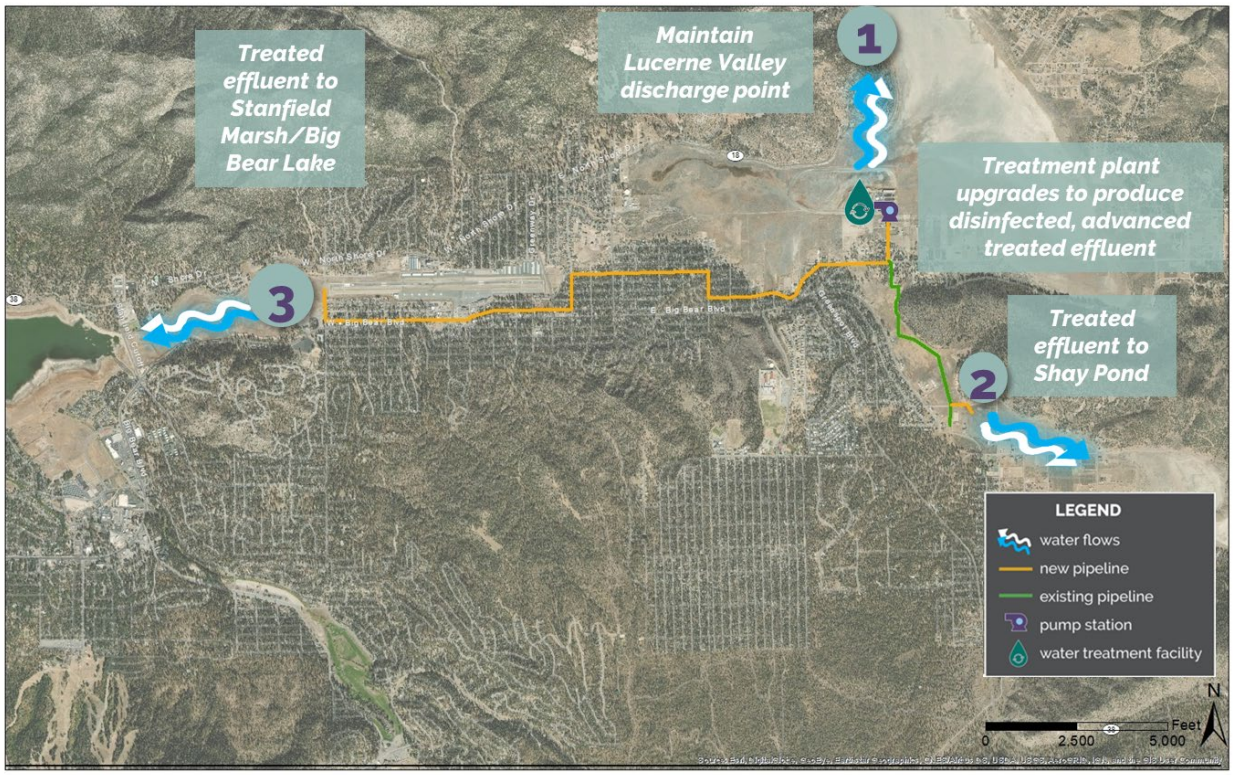

Figure ES - 1. Replenish Big Bear Program Lake and Shay Pond Discharge Locations

Water Quality Impacts of Proposed Discharges

The Replenish Big Bear Program Lake discharge is anticipated to improve Lake water quality for total dissolved solids (TDS), total phosphorus (TP), total nitrogen (TN), and chlorophyll-a as compared to modeled baseline (no project) conditions, and result in similar water quality for total inorganic nitrogen (TIN) as compared to the modeled baseline. In addition, the proposed discharge is anticipated to feature concentrations similar to or lower than ambient water quality and the most stringent WQO or criterion for all constituents evaluated except for boron. For boron, concentrations in the Lake are anticipated to increase as compared to baseline conditions, but remain well below the most stringent WQO of 0.75 mg/L.

The Shay Pond discharge is anticipated to be of better quality than the current potable water supply and ambient water quality for most constituents of interest. However, additional data may be needed to confirm these findings. Like the Lake discharge, boron may be the only constituent in the disinfected, advanced treated effluent discharged to Shay Pond that could be above existing ambient water quality for the constituent. However, it is well below the WQO of 0.75 mg/L that exists for the protection of water used to irrigate boron-sensitive agricultural crops, which is not a use of the water in Shay Pond. Additional coordination with the California Department of Fish and Wildlife (CDFW) will be conducted to ensure the Unarmored Threespine Stickleback (Stickleback) fish, a federally and State listed endangered species, and located in Shay Pond are protected.

Consistency with Antidegradation Policies

The proposed project, the discharge of disinfected, advanced treated BBARWA effluent to (1) Stanfield Marsh/ Lake at a discharge rate up to 2,210 AFY and (2) Shay Pond at a discharge rate up to 80 AFY, is determined to comprise best practicable treatment and control and is consistent with federal and State antidegradation policies for the following reasons:

- The proposed discharge to both Stanfield Marsh/ Lake and Shay Pond will not adversely affect existing or probable beneficial uses of either receiving water or downstream receiving waters, nor will the discharges cause water quality to not meet applicable water quality objectives.
- Overall, the proposed discharge is estimated to improve water quality in the Lake for TDS, TN, TP, and chlorophyll-a, maintain similar water quality for TIN, and have a very minor impact on boron. Future boron concentrations in the Lake are estimated to increase very slightly due to the proposed BBARWA discharge but are estimated to remain well below the 0.75 mg/L Basin Plan objective for boron (see **Table 7** and **Section 5.3.2**). The Lake Analysis shows that projected ambient Lake concentrations of TIN and chlorophyll-a with the proposed discharge will exist below their relevant WQO (TIN) or TMDL target (chlorophyll-a). The Lake Analysis also shows that ambient Lake concentration of TDS and TP with the proposed discharge are estimated to exceed the 175 mg/L TDS WQO and the 35 µg/L TP TMDL target, respectively. However, the modeled baseline (no project) condition is projected to result in Lake concentrations for TDS, TP, TIN, and chlorophyll-a that exceed those concentrations more often than all modeled BBARWA discharge scenarios. Modeled results for the proposed BBARWA discharge, when combined with a TP Offset Program (see Attachment B of the ROWD package), show the greatest improvements to future, ambient Lake concentrations as compared to the modeled baseline (no project) condition.

- Overall, the proposed BBARWA discharge is estimated to have a very minor impact on Shay Pond water quality and Shay Creek water quality downstream of the pond. The proposed project is estimated to potentially cause a very minor increase in boron concentrations in the pond and downstream in Shay Creek, but concentrations are estimated to remain well below the 0.75 mg/L Basin Plan objective for boron. The disinfected, advanced treated effluent proposed for discharge to the pond is anticipated to lower the concentrations of those constituents listed in **Table 13** as compared to existing ambient concentrations that are largely influenced by the groundwater currently discharged by BBCCSD to the pond to maintain water levels for the endangered Stickleback.
- Based on the above, the request to permit a new discharge to both Stanfield Marsh/ Lake and Shay Pond is consistent with federal and State antidegradation policies in that the minor lowering of water quality boron in the Lake (see **Table 7**) and Shay Pond (see **Table 13**) is necessary to accommodate important economic or social development[1], will not unreasonably affect beneficial uses, will not cause further exceedances of applicable WQOs, and is consistent with the maximum benefit to the people of the State.
- Based on the above, the request to permit new discharges to Stanfield Marsh/ Lake and Shay Pond are consistent with the Porter-Cologne Act in that the resulting water quality will constitute the highest water quality that is reasonable, considering all demands placed on the waters, economic and social considerations, and other public interest factors.

The proposed discharge of disinfected, advanced treated BBARWA effluent to Stanfield Marsh/ Lake and Shay Pond also fully supports California's *Recycled Water Policy* (SWRCB, 2013) in that it would result in an increased use of recycled water from municipal wastewater sources, would incrementally reduce reliance on the vagaries of annual precipitation, and would assist in the sustainable management of surface and groundwater resources.

[1] Maintain and improve recreation and tourism in the Big Bear Lake region which in turn stimulates the local and regional economies.

1 INTRODUCTION

This section provides an overview of the Replenish Big Bear Program, description of the proposed discharges to Stanfield Marsh, a tributary of the Lake, and a separate discharge to Shay Pond, a tributary of Shay Creek. This section also discusses the purpose and approach used in this antidegradation analysis report.

1.1 Program Overview

BBARWA is a joint powers authority formed in 1974 to provide centralized wastewater conveyance, treatment, and disposal for the City of Big Bear Lake, representing approximately 47% of the total connections, BBCCSD, representing approximately 48% of the total connections, and County of San Bernardino Service Area 53B (CSA53), representing approximately 5% of the total connections. Each of these member agencies maintains and operates its own wastewater collection system that conveys wastewater to BBARWA's interceptor system for transport to the BBARWA WWTP. The BBARWA service area includes the entire Valley and covers about 79,000 acres. BBARWA owns and operates a regional WWTP to treat the Valley's wastewater and currently discharges undisinfected secondary effluent to Lucerne Valley, which is located outside the Santa Ana Watershed.

The Replenish Big Bear Program is a collaborative regional water resources program being implemented by Agency Team to help protect the Valley and the Santa Ana Watershed from the impacts of drought and variable precipitation through the recovery of this local water resource currently discharged outside of the watershed.

The Replenish Big Bear Program is comprised of three independent projects:

1) Discharge of disinfected, advanced treated effluent to Stanfield Marsh, which is tributary to the Lake, and a separate discharge to Shay Pond;
2) Use of Lake water for purposes such as landscape irrigation of the local golf course, construction uses and snowmaking; and
3) Use of Lake water for groundwater recharge in Sand Canyon.

The first project is the subject of this antidegradation analysis and is foundational to the Replenish Big Bear Program and necessary to enable implementation of the subsequent uses of Lake water. As part of the first project, the BBARWA WWTP will be upgraded to produce disinfected, advanced treated effluent through tertiary filtration using ultrafiltration, and RO treatment with UV disinfection for the proposed discharges to the Lake and Shay Pond.

Although the proposed Lake discharge will be physically discharged at the east end of Stanfield Marsh, then flow through the Marsh into the Lake through a set of culverts under Stanfield Cutoff, this antidegradation analysis was completed for the Lake since Stanfield Marsh has been mostly dry since 2015. Therefore, current ambient water quality data is not available for this antidegradation analysis. Additionally, the WQOs specified for the Lake in the Basin Plan are more stringent than those for Stanfield Marsh.

Figure 1 shows the WWTP and proposed discharge locations, which are components of the first project. The proposed project's two discharge points will allow BBARWA to minimize the discharge of disinfected, advanced treated effluent outside of the watershed. The Lake discharge will increase Lake levels to better support beneficial uses including recreation and habitat, particularly during times of drought. The Shay Pond discharge will replace potable water currently discharged to the waterbody to maintain the water flow through the pond. Up to 80 AFY of disinfected, advanced treated effluent will be sent to Shay Pond, and any remaining disinfected, advanced treated effluent will be sent to the Lake.

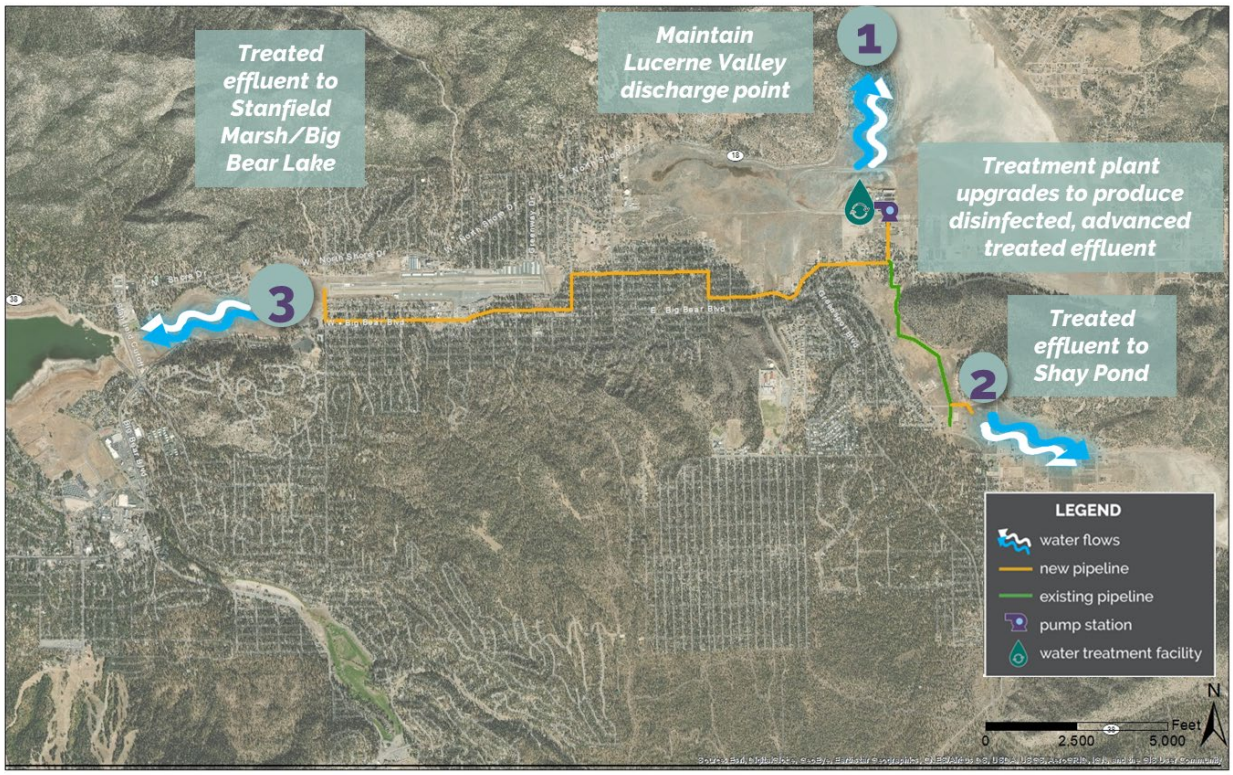

Figure 1. Replenish Big Bear Program Lake and Shay Pond Discharge Locations

The other two projects will utilize Lake water for purposes such as1) landscape irrigation, construction uses, and snowmaking at the ski resort, and 2) direct groundwater recharge in Sand Canyon. **Figure 2** shows the general location of these two projects. The golf course irrigation, construction uses, and snowmaking project can be implemented using existing infrastructure used for snowmaking that draws water from the Lake. The Sand Canyon recharge project will require construction of a pump station, pipeline, recharge ponds and monitoring wells and may be implemented in parallel with the Lake discharge.

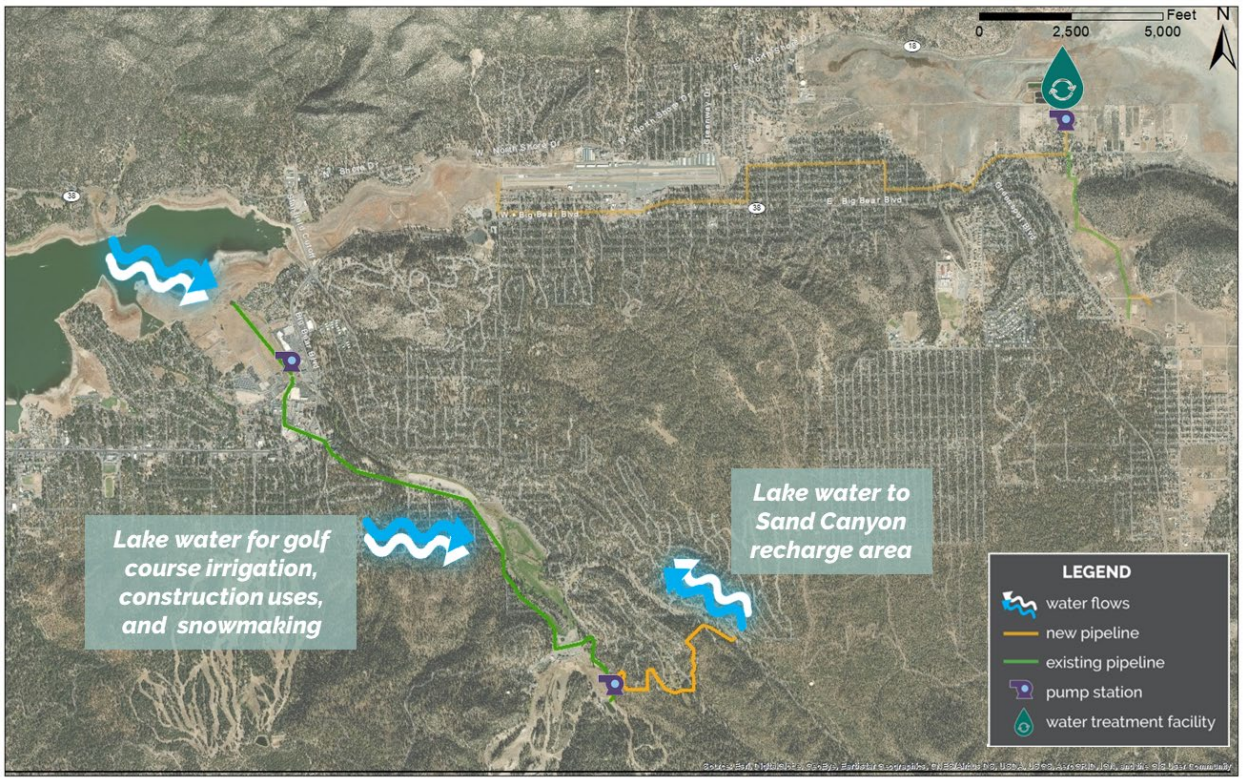

Figure 2. Replenish Big Bear Program Subsequent Uses of Lake Water

1.2 Project Description

The discharge of disinfected, advanced treated effluent to Stanfield Marsh, which is tributary to the Lake, and a separate discharge to Shay Pond is the subject of this antidegradation analysis. The proposed discharges require the construction of WWTP upgrades, an effluent booster pump station at the WWTP site and approximately seven (7) miles of pipeline to convey water to the discharge locations.

Figure 3 shows a process flow diagram of the existing BBARWA WWTP treatment process.

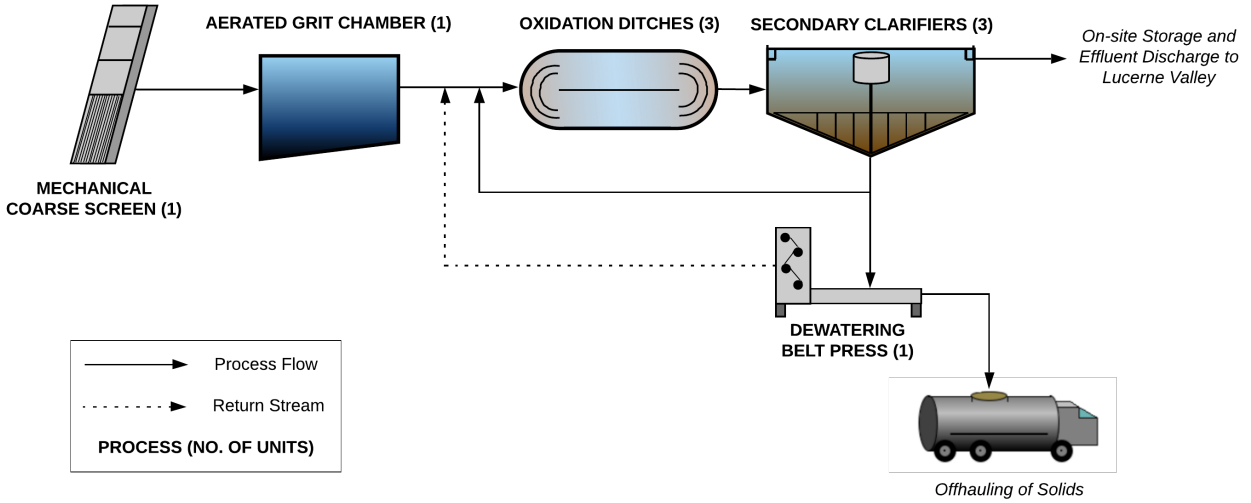

Figure 3. BBARWA Existing WWTP Process Flow Diagram

The existing BBARWA WWTP secondary treatment facility has a capacity of 4.89 MGD and a hydraulic capacity of 9.1 MGD. The WWTP treats commercial and domestic wastewater from the City of Big Bear Lake, BBCCSD, and CSA53 collection systems. The existing treatment process includes the following:

- Preliminary treatment consisting of a mechanical coarse screen and an aerated grit chamber;
- Secondary treatment consisting of extended aeration oxidation ditches and secondary clarifiers; and
- Solids handling through a dewatering belt filter press.

Treated effluent is temporarily stored on-site prior to discharge to Lucerne Valley and dewatered solids are hauled off-site. The undisinfected secondary effluent discharged to Lucerne Valley is currently used to irrigate crops used for livestock feed. This discharge is regulated under Order R7-2021-0023 Waste Discharge Requirements (WDR) permit, issued by the Colorado River Basin Regional Water Quality Control Board (**Appendix A**).

The proposed upgrades, as shown in **Figure 4**, to the BBARWA WWTP to produce disinfected, advanced treated effluent include:

- Biological nutrient removal improvements to the existing oxidation ditches for improved nitrification and denitrification;
- Tertiary filtration and nitrogen and phosphorus removal via denitrification filters;

- Low- and high-pressure filtration with ultrafiltration (UF) membranes and 90% recovery RO membranes;
- Brine pellet reactor for brine minimization to produce a total system recovery of 99%; and
- UV disinfection.

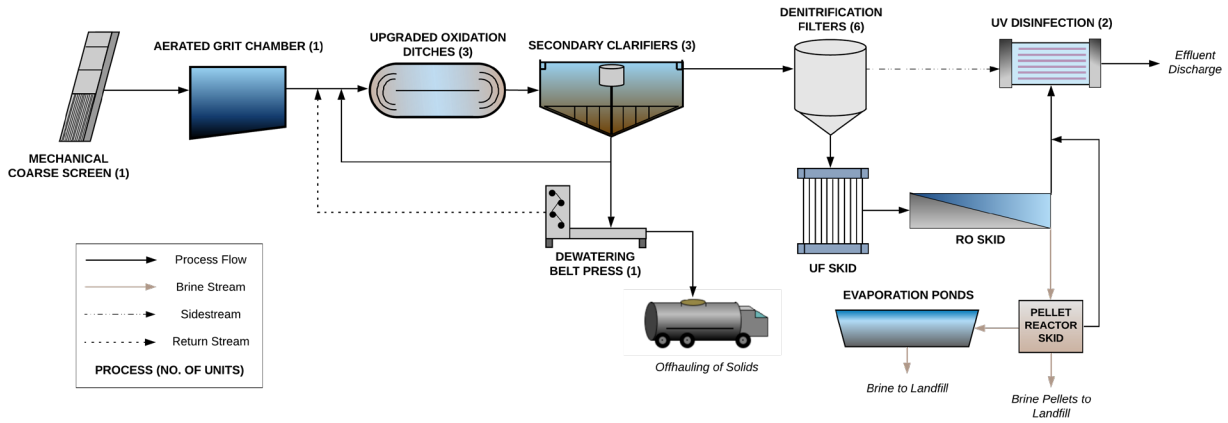

Figure 4. BBARWA Proposed WWTP Treatment Upgrades Flow Diagram

The proposed upgrades (i.e., new advanced treatment train) would be designed for a treatment capacity of 2.2 MGD. By 2040, accounting for expected growth, it is estimated that the WWTP could produce 2,210 AFY of advanced treated effluent, assuming a 99% total recovery rate could be achieved (90% RO recovery and 90% recovery of brine through brine minimization). The WWTP currently produces about 2.0 MGD of undisinfected secondary effluent on an average annual basis.

The RO brine management option included in the preliminary design for Replenish Big Bear is a brine minimization pellet reactor to reduce the volume of brine produced by the RO process. The reduced brine stream from the pellet reactor will be conveyed to evaporation ponds located on BBARWA WWTP property. It is assumed that an RO recovery of 90% at 2.2 MGD influent flow would result in 0.22 MGD of RO brine to be minimized through the pellet reactor and approximately 0.022 MGD of liquid brine to be conveyed to the evaporation pond based on a pellet reactor recovery of 90%. A total evaporation pond area of 23 acres is needed for the brine stream. The RO brine management strategy will be evaluated further as the Project enters the design phase, along with refinements to total system recoveries based on site-specific piloting results.

BBARWA also plans to maintain the existing Lucerne Valley discharge location. All WWTP process water in excess of the new treatment train's 2.2 MGD capacity will continue to be treated to undisinfected secondary levels and conveyed to the existing Lucerne Valley site, consistent with the current, permitted discharge requirements of the existing BBARWA WWTP.

1.3 Purpose of Report

As required by the Clean Water Act (CWA), the discharge of any pollutant or combination of pollutants to surface waters that are deemed waters of the United States (U.S.), as is the Lake discharge and potentially Shay Pond discharge, must be regulated by a National Pollutant Discharge Elimination System (NPDES) permit. Because the two proposed discharge locations are new discharges to surface waters of the U.S., a NPDES permit governing the proposed discharges must be requested from the Regional Water Board.

Under the State and federal antidegradation policies, the Regional Water Board is required to make a finding regarding the satisfaction of the policies as they pertain to surface water discharges for which the Regional Water Board issues a NPDES permit. The State antidegradation policy, which incorporates the federal antidegradation policy, seeks to maintain the existing high quality of water to the maximum extent possible, and only allows a lowering of water quality if:

- Changes in water quality are consistent with maximum benefit to the people of the state, will not unreasonably affect present and potential beneficial uses, and will not result in water quality lower than applicable standards, and
- Waste discharge requirements for a proposed discharge will result in the best practicable treatment or control of the discharge necessary to assure:
    - No pollution or nuisance; and
    - Highest water quality consistent with maximum benefit to the people of the State.

The purpose of this report is to provide the Regional Water Board with the information needed to determine whether the proposed discharges are consistent with State and federal antidegradation policies. This antidegradation analysis includes assessments of water quality impacts on the receiving waters and downstream receiving waters estimated to result from the proposed project; an evaluation of how these estimated changes in water quality compare to applicable WQO and relevant water quality criteria; how estimated changes in water quality may affect existing or probable beneficial uses; and a finding of consistency with antidegradation policies.

1.4 Analysis Approach

The following antidegradation analysis is tailored to be consistent with federal and State antidegradation policies and the guidance provided in the Administrative Procedures Update (APU) 90-004. Pursuant to the APU guidelines, this analysis follows the provisions for a "simple analysis" and evaluates whether changes in water quality resulting from the proposed new discharges to the Lake and Shay Pond are "*consistent with maximum benefit to the people of the State, will not unreasonably affect uses and will not cause water quality to be less than water quality objectives and that the discharge provides protection of existing in-stream beneficial uses and water quality necessary to protect those uses.*"

In general, the data available for existing secondary effluent quality, projected disinfected advanced treated effluent quality, and ambient water quality were assessed to determine if the proposed future discharge would result in concentrations that exceed existing ambient water quality and/or relevant WQOs or criteria. For constituents anticipated to lead to a lowering of existing ambient water quality or an exceedance of relevant WQOs or criteria, further analysis was conducted.

Additionally, TDS, TIN, TN, TP, and chlorophyll-a were evaluated using a two dimensional (2D) hydrodynamic-water quality model (CE-QUAL-W2) developed for Big Bear Lake by Dr. Michael A. Anderson (Dr. Anderson), a limnologist who has in-depth knowledge of the Lake. The model evaluation was conducted to help select the preferred treatment alternative and assess the impacts of the proposed Lake discharge on constituents of interest. The water quality impacts with and without the proposed project were assessed for three different treatment alternatives as documented in *Big Bear Lake Analysis: Replenish Big Bear* (2021 Lake Model Analysis; **Appendix B**). Additional model updates were recently completed to incorporate additional discharge volume scenarios and seasonal variability and documented in *Replenish Big Bear: Modeling of Higher Flows and with Zero TP Load* (2022 Lake Model Update; **Appendix C**). The model results from both analyses are discussed in this report.

For constituents not able to be evaluated by the CE-QUAL-W2 model, their potential impacts with regard to a lowering of existing ambient water quality and/or the exceedance of relevant WQOs or criteria were assessed using a simple mass balance equation.

2 REGULATORY REQUIREMENTS

This section summarizes the federal and State antidegradation policies considered in this antidegradation analysis.

2.1 Applicable Laws and Policies

The federal Clean Water Act (CWA) requires states to adopt, with United States Environmental Protection Agency (U.S. EPA) approval, water quality standards applicable to all intrastate waters (33 U.S.C. § 1313). U.S. EPA regulations also require state water quality standard submittals to include an antidegradation policy to protect beneficial uses and prevent further degradation of high-quality waters (33 U.S.C. § 1313(d)(4)(B); 40 C.F.R. § 131.12). The State's antidegradation policy is embodied in State Water Resources Control Board (SWRCB) Resolution 68-16.

BBARWA's requested discharge of disinfected, advanced treated effluent to the Lake and to Shay Pond requires the application of WQOs contained in the Basin Plan, as well as criteria promulgated by the U.S. EPA for California waters. Both the federal and State antidegradation policies apply to the proposed surface water discharges of treated effluent to the Lake and to Shay Pond.

2.2 Federal Policies and Guidance

The federal antidegradation policy is designed to protect existing uses and the level of water quality necessary to protect existing uses and provide protection for higher quality and outstanding national water resources. The federal policy directs states to adopt a statewide policy that includes the following primary provisions (40 C.F.R. § 131.12).

1) *Existing in-stream water uses and the level of water quality necessary to protect the existing uses shall be maintained and protected.*

2) *Where the quality of waters exceeds levels necessary to support propagation of fish, shellfish, and wildlife and recreation in and on the water, that quality shall be maintained and protected unless the State finds, after the full satisfaction of the intergovernmental coordination and public participation provisions of the State's continuing planning process, that allowing lower water quality is necessary to accommodate important economic or social development in the area in which the waters are located. In allowing such degradation or lower water quality, the State shall assure water quality adequate to protect existing uses fully. Further, the State shall assure that there shall be achieved the highest statutory and regulatory requirements for all new and existing point sources and all cost effective and reasonable best management practices for nonpoint source control*

3) *Where high quality waters constitute an outstanding National resource, such as water of National and State parks and wildlife refuges and waters of exceptional recreational or ecological significance, that water quality shall be maintained and protected.*

4) *In those cases where potential water quality impairment associated with a thermal discharge is involved, the antidegradation policy and implementing method shall be consistent with Section 316 of the Act.*

Based on guidance developed by the U.S. EPA, Region 9 (Guidance on Implementing the Antidegradation Provisions of 40 C.F.R. § 131.12 (U.S. EPA, 1987)) and guidance issued by SWRCB with regard to application of the Federal Antidegradation Policy (Memorandum from William R. Attwater to Regional Board Executive Officers Federal Antidegradation Policy (Attwater, Oct. 1987)), application of the federal antidegradation policy is triggered by a lowering, or potential lowering, of surface water quality. A proposed increase in the volume of an existing discharge or a new discharge to surface water is typically considered a trigger to the application of the federal antidegradation policy. Because the Project is proposing two new discharges to surface waters, the federal antidegradation policy applies.

Both the Lake and Shay Pond are not designated as outstanding natural resource waters and therefore, the receiving waters are not subject to that portion of the federal policy. The application to other portions of the policy is determined on a constituent-by-constituent basis. For a water body where water quality is not significantly better than needed to meet designated uses, either because it does not meet or it just meets applicable water quality objectives or criteria to protect beneficial uses, a new discharge cannot cause further impairment.

For waters with water quality that is better than necessary to support beneficial uses, the new discharge may not lower water quality unless such lowering is necessary to accommodate important economic or social development. In August 2005, the U.S. EPA issued a memorandum discussing antidegradation reviews and significance thresholds (Memorandum from Ephraim S. King, Director, Office of Science and Technology, U.S. EPA, Office of Water to Water Management Division Directors, Regions 1-10 (August 2005). As discussed in the memorandum, an intent of the policy "is to maintain and protect high quality waters and not to allow for any degradation beyond a *de minimis* level without having made a demonstration, with opportunity for public input, that such lowering is necessary and important." (Memorandum at p. 1). U.S. EPA has determined that the significance threshold of a 10% reduction in available assimilative capacity is "workable and protective in identifying those significant lowering of water quality that should receive a full… antidegradation review, including public participation." (U.S. EPA, 2005). This determination by U.S. EPA is helpful in determining the magnitude of water quality change that is determined to be of significant interest in the antidegradation analysis.

2.3 State Policies and Guidance

2.3.1 Resolution 68-16

The State issued its own antidegradation policy in 1968 to protect and maintain existing water quality in California. The State's Resolution 68-16 is interpreted to incorporate the federal antidegradation policy and satisfies the federal regulation requiring states to adopt their own antidegradation policies. Resolution 68-16 states, in part:

1) *Whenever the existing quality of water is better than the quality established in policies as of the date on which such policies become effective, such existing high quality will be maintained until it has been demonstrated to the State that any change will be consistent with maximum benefit to the people of the State, will not unreasonably affect present and anticipated beneficial uses of such water and will not result in water quality less than that prescribed in the policies.*

2) *Any activity which produces or may produce a waste or increased volume or concentration of waste and which discharges or proposes to discharge to existing high quality water will be required to meet waste discharge requirements which will result in the best practicable treatment or control of the discharge necessary to assure that (a) a pollution or nuisance will not occur and (b) the highest water quality consistent with maximum benefit to the people of the State will be maintained.*

2.3.2 1987 Policy Memorandum

In 1987, SWRCB issued a policy memorandum to the Regional Water Quality Control Boards (Regional Water Boards) to provide guidance on the application of the federal antidegradation policy for State and Regional Water Board actions, including establishing water quality objectives, issuing NPDES permits, and adopting waivers and exceptions to water quality objectives or control measures (Attwater, 1987). In conducting these actions, the Regional Water Boards must assure protection of existing beneficial uses, that significant lowering of water quality is necessary to accommodate important economic or social development, and that outstanding national resource waters be maintained and protected. The 2005 U.S. EPA guidance referenced in the Federal Policies and Guidance Section above is useful in determining whether changes in water quality that may result from a proposed action are significant.

2.3.3 Administrative Procedures Update (APU) 90-004

SWRCB issued guidance (APU 90-004) to all Regional Water Boards in 1990 regarding the implementation of State and federal antidegradation policies in NPDES permits. By using this guidance, Regional Water Boards are to determine if a proposed discharge is consistent with the intent and purpose of the State and federal antidegradation policies. APU 90-004 provides Regional Water Boards with guidance on the appropriate level of analysis that may be necessary, distinguishing between the need for a "simple" antidegradation analysis and a "complete" antidegradation analysis. If it is determined that a simple analysis is not appropriate based on the estimated level of impact of the new discharge, then a more rigorous analysis – a complete analysis – is appropriate. A primary focus of the complete analysis is the determination of whether and the degree to which water quality is lowered as compared to the socioeconomic costs of maintaining existing water quality. This determination greatly influences the level of analysis required and the level of scrutiny applied to the "balancing test" – that is, whether the discharge is necessary to accommodate important economic and social development, and whether a water quality change is consistent with the maximum benefit to the people of the State.

The antidegradation analysis addresses the following questions stated in SWRCB APU 90-004 to maintain consistency with State and federal antidegradation policies.

- Whether a reduction in water quality will be spatially localized or limited with respect to the water body; e.g., confined to the mixing zone;
- Whether the proposed discharge of treated effluent will produce minor effects which will not result in a significant reduction of water quality;

- Whether the proposed discharge of treated effluent has been approved in a General Plan, or similar growth and development policy document, and has been adequately subjected to the environmental analysis required in an environmental impact report (EIR) required under the California Environmental Quality Act (CEQA); and
- Whether the proposed Project is consistent with maximum benefit to the people of the State.

The Replenish Big Bear Program seeks to discharge highly treated effluent receiving RO treatment and UV disinfection to the Lake and to Shay Pond. BBARWA has reviewed the NPDES guidance issued by SWRCB in APU 90-004 and believes that the proposed project meets the criteria for a simple antidegradation analysis. The following sections provide the rationale for this determination and an associated level of analysis and information for use by the Regional Water Board in its consideration of state and federal antidegradation requirements in accordance with APU 90-004.

3 APPLICABLE WATER QUALITY STANDARDS

This section summarizes the applicable water quality standards for Stanfield Marsh and the Lake. Stanfield Marsh and the Lake are both waters of U.S., which have several designated beneficial uses. Water quality standard applicable to Shay Pond are discussed in **Section 6**. **Figure 5** shows the proposed discharge location in reference to Stanfield Marsh and Lake.

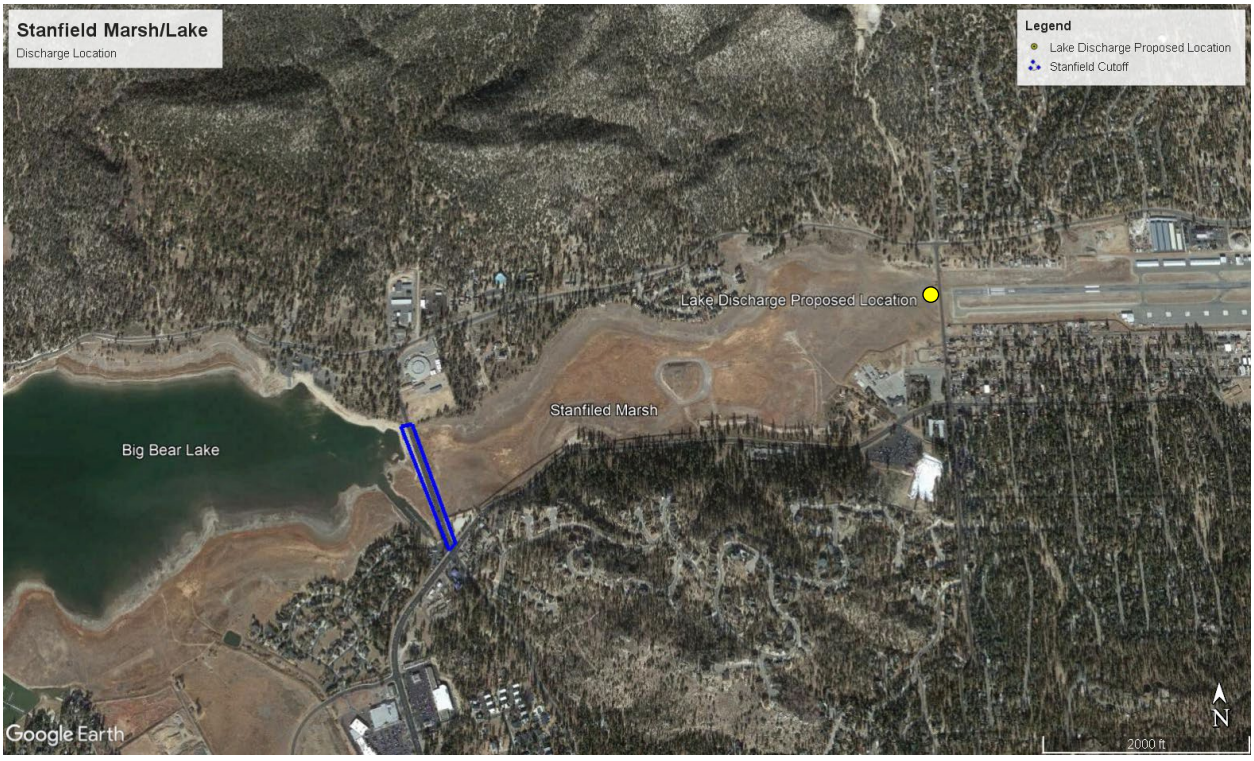

Figure 5. Overview of Lake Discharge Location in Reference to Stanfield Marsh/Lake

3.1 Beneficial Uses

The Basin Plan contains descriptions of the legal, technical, and programmatic bases for water quality regulation in the Santa Ana region. The Basin Plan describes the beneficial uses of major surface waters and their tributaries and the corresponding WQOs put into effect to protect these beneficial uses. **Table 1** shows the designated beneficial uses of the Lake and Stanfield Marsh.

Table 1. Beneficial Uses of Lake and Stanfield Marsh

Beneficial Uses	Big Bear Lake	Stanfield Marsh
AGR - Agricultural Supply	✓	
COLD - Cold Freshwater Habitat	✓	✓
GWR - Groundwater Recharge	✓	
MUN - Municipal and Domestic Supply	✓	✓
RARE - Rare, Threatened, or Endangered Species	✓	✓
REC1 - Water Contact Recreation	✓	✓
REC2 - Non-Contact Water Recreation	✓	✓
SPWN - Spawning, Reproduction, and/or Early Development	✓	
WARM - Warm Freshwater Habitat	✓	
WILD - Wildlife Habitat	✓	✓

3.2 Water Quality Objectives/Water Quality Criteria

To protect the designated beneficial uses, the Regional Water Board applies WQOs contained in the Basin Plan and criteria adopted in the California Toxics Rule (CTR) and the National Toxics Rule (NTR) to the receiving water (i.e., Lake) and downstream receiving waters (i.e., Bear Creek and subsequently Santa Ana River Reach 6). Per the Basin Plan, Stanfield Marsh does not have numeric WQOs. The Lake WQO objectives were used since these are more stringent and the Stanfield Marsh has been mostly dry since 2015.

The Regional Water Board uses these standards to determine if a proposed project will cause or contribute to impairments of the designated beneficial uses. **Table 2** presents the most conservative water quality criteria used to protect the most sensitive beneficial uses that apply to the Lake and downstream receiving waters. The constituents of interest included in **Table 2** are those:

- Included in the Basin Plan;
- Listed in the California 2018 Integrated Report for CWA Section 303(d) list;
- Identified by the Regional Water Board as pollutants of particular concern; and

- Constituents for which a Total Maximum Daily Load (TMDL) exists.

Table 2. Applicable WQOs and/or Criteria for the Lake Discharge

Constituent	Most Stringent WQO or Criterion	Unit	Reference for Most Stringent WQO or Criterion
Ammonia as N	0.46	mg/L	Basin Plan; used Basin Plan Table 4-4 (a)
Boron, Total	0.75	mg/L	Basin Plan(b)

Notes: Bolded constituents were identified as constituents of interest by the Regional Water Board and were modeled in the Lake Analysis (**Appendix B** & **C** and discussed in **Section 5.3.1.**

a) The total ammonia was estimated using the equation presented in Table 4-4 of the Basin Plan. The Lake wide average pH is 8.28 based on the 2009-2019 TMDL data collected. The Lake water temperature ranges between 35 °F (1.8°C) and 70°F (20.7°C). The average Lake water temperature used is 53°F (11.8°C).
b) Boron concentrations shall not exceed 0.75 mg/L in inland surface waters of the region as a result of controllable water quality factors.

Constituent	Most Stringent WQO or Criterion	Unit	Reference for Most Stringent WQO or Criterion
c) Annual average concentration determined based on daily air temperature between 17.7-21.4 °C. d) MBAS concentrations shall not exceed 0.05mg/L in inland surface waters designated MUN as a result of controllable water quality factors. It is a secondary drinking water standard. e) Value is being considering by the Regional Water Board, as potential target. f) California Toxics Rule (CTR) hardness-based criterion continuous concentration (CCC) calculated using a median total hardness value of 99 mg/L calculated from measurements made in the Santa Ana River, Reach 6, upstream of Seven Oaks Dam, 2000-2006. g) Constituent added as it was detected in the secondary effluent and Lake.			

The Basin Plan contains both numeric and narrative objectives for inland surface waters, which were used to evaluate the Lake discharge. For this analysis, some of the narrative objectives were not evaluated for the following reasons:

- Algae, floatable, oil and grease, solids (suspended and settleable), sulfides, and surfactants were not evaluated because the Basin Plan does not specify numeric limits so these parameters could not be compared;
- Chlorine residual because chlorine will not be used for disinfection at the BBARWA WWTP;
- Chemical oxygen demand , dissolved oxygen, pathogen indicator bacteria, radioactivity material, color, temperature, and taste and odor because these are assumed to be non-conservative constituents (i.e., presumed to be destroyed, consumed, biodegraded or transformed through the treatment process or through Stanfield Marsh). The treatment process includes low- and high-pressure membrane systems capable of producing effluent that meets or exceeds the objectives for inland surface waters for these constituents, to be confirmed with site-specific piloting of the treatment process;
- Nitrate as N since the TN value being considered by the Regional Board is more stringent than the recommended 10 mg/L in Basin Plan; and
- pH because the treatment process maintains a neutral pH between 7 and 8 upstream of the reverse osmosis process, and then become slightly acidic downstream of reverse osmosis. Reverse osmosis chemical post-treatment will be employed to adjust the pH to a neutral level such that the effluent is within the numerical objectives for pH. In general, the pH of inland surface waters shall not be raised above 8.5 or depressed below 6.5 as a result of controllable water quality factors.

3.3 303 (d) Listings

Section 303(d) of the CWA requires states to develop lists of water bodies (or segments of water bodies) that will not attain water quality standards after implementation of minimum required levels of treatment by point-source dischargers (i.e., municipalities and industries). Section 303(d) requires states to develop a TMDL for each of the listed pollutant and water body combinations for which there is impairment. A TMDL is the amount of loading that the water body can receive and still meet water quality standards for that pollutant. The TMDL must include an allocation of allowable loadings for both point and non-point sources, with consideration of background loadings and a margin of safety. NPDES permit limitations for listed pollutants must be consistent with allocations identified in adopted TMDLs.

The U.S. EPA approved the California's 2018 Integrated Report for CWA Sections 305 (b) and 303(d) on June 9, 2021 (SWRCB, 2021). This list represents the most current listing of impaired water bodies in the project area and downstream areas. The Lake is included in the California's 2018 Section 303(d) list of impaired water bodies for mercury, nutrients, noxious aquatic plants, dichlorodiphenyltrichloroethane (DDT), chlordane, and polychlorinated biphenyls (PCBs). The Santa Ana River (SAR) Reach 6, which is located about 17 miles downstream from the Lake, is also listed for cadmium, lead, and copper. The potential water quality impacts of the proposed Lake discharge are discussed in **Section 5.**

Table 3 lists the constituents identified in the 2018 303(d) list for the Lake and SAR Reach 6, and their potential sources and proposed TMDL completion dates.

Table 3. 2018 CWA Section 303(d) Listed Constituents

Pollutant/Stressor	Potential Sources	Proposed TMDL Adoption
Lake		
Mercury	Source Unknown	2007
Nutrients	Construction/Land Development	Completed
Noxious aquatic plants	Source Unknown	Completed
DDT	Source Unknown	2027
Chlordane	Source Unknown	2027
PCBs	Source Unknown	2019
Santa Ana River Reach 6		
Cadmium	Source Unknown	2021
Lead	Source Unknown	2021
Copper	Source Unknown	2021

3.4 Lake Nutrient TMDL

The Big Bear Lake Nutrient Total Maximum Daily Load (Nutrient TMDL) for Dry Hydrologic Conditions (Resolution No. R8-2006-0023) was adopted by the Regional Water Board on April 21, 2006 and became effective on September 25, 2007. The Nutrient TMDL includes targets in the Lake for TP, macrophyte coverage, nuisance aquatic vascular plant species, and chlorophyll-a. **Table 4** shows the Nutrient TMDL targets. TP is the only constituent that would be directly discharged and controlled by BBARWA.

Table 4. Nutrient TMDL Numeric Targets for All Hydrologic Conditions

Indicator	Target Value [a][b]
TP Concentration [c]	Annual average no greater than 35 µg/L
Macrophyte Coverage[d]	30-40% on a total lake area basis
Percentage of Nuisance Aquatic Vascular Plant Species[d][e]	95% eradication on a total area basis of Eurasian Water milfoil and any other invasive aquatic plant species
Chlorophyll-a Concentration[e]	Growing season average no greater than 14 µg/L

Source: Basin Plan

Notes:

a) Targets to be attained no later than 2015 (dry hydrological conditions), 2020 (all other conditions)

b) Compliance date for wet and/or average hydrological conditions may change in response to approved TMDLs for wet/average hydrological conditions.

c) Annual average determined by the following methodology: the nutrient data from both the photic composite and discrete bottom samples are averaged by station number and month; a calendar year average is obtained for each sampling location by averaging the average of each month; and finally, the separate annual averages for each location are averaged to determine the lake-wide average.

d) Calculated as a 5-yr running average based on measurements taken at peak macrophyte growth.

e) Growing season is the period from May 1 through October 31 of each year. The chlorophyll-a data from the photic samples are averaged by station number and month; a growing season average is obtained for each sampling location by averaging the average of each month; and finally, the separate growing season averages for each location are averaged to determine the lake-wide average.

An analysis to demonstrate that the proposed Lake discharge is consistent with the Nutrient TMDL assumptions is provided in Attachment B of the ROWD package**.** This technical memorandum (TM) also discusses a TP offset framework to address the lack of wasteload allocation (WLA) for the proposed Lake discharge by proposing a TP net zero load. The TM also discusses the effects of the Lake discharge and TP Offset Program on chlorophyll-a, the response target, as documented in the Lake Analysis (**Appendix B**) and new model updates (**Appendix C**).

3.5 Statewide Mercury Provisions

On May 2, 2017, the California State Water Resources Control Board (State Water Board) adopted Resolution 2017-0027, which approved "*Part 2 of the Water Quality Control Plan for Inland Surface Waters, Enclosed Bays, and Estuaries of California—Tribal and Subsistence Fishing Beneficial Uses and Mercury Provisions.*" Resolution 2017-0027 established mercury limits to protect the beneficial uses associated with the consumption of fish by both people and wildlife. For lakes and reservoirs, the mercury water column concentration is to be calculated by the permitting authority (i.e., Regional Water Board). The mercury limit for the Lake has not yet been established. However, the State Water Board is also developing a Statewide Mercury Control Program for Reservoirs that are impaired for mercury. The draft "*2017 Amendment to the Water Quality Control Plan for Inland Surface Waters, Enclosed Bays, and Estuaries of California—Mercury TMDL and Implementation Program for Reservoirs,*" proposes to establish WLAs of 10 ng/L for major WWTPs (permitted flow >1 MGD), and a WLA of 20 ng/L for facilities with no "upstream" dischargers. The Statewide Mercury Provisions identified the Lake as one of the 131 impacted reservoirs. For this analysis, the 10 ng/L WLA was considered for evaluation with respect to potential water quality impacts due to the proposed Lake discharge.

3.6 Title 22 Recycled Water Criteria

Per conversations with DDW, the Lake may be designated as a non-restricted recycled water impoundment and the subsequent use of Lake water for snowmaking, landscape irrigation, construction uses, and groundwater recharge would be subject to recycled water regulations. Additional coordination and studies are being conducted to regulate these uses. It is anticipated that a separate WDR permit will be obtained to regulate the Sand Canyon groundwater recharge project. The non-potable recycled water uses for landscape irrigation, construction uses, snowmaking, and nonrestricted impoundment are anticipated to be regulated under the Statewide Water Reclamation Requirements for Recycled Water Use (Oder WQ 2016-0068-DDW).

4 ENVIRONMENTAL SETTING

This section provides additional context to understand the enviromental setting for the Lake discharge.

4.1 Stanfield Marsh

As part of Replenish Big Bear, the proposed project will discharge to the east end of Stanfield Marsh, then flow into the Lake, as shown in **Figure 5**.

Stanfield Marsh in 2016

Stanfield Marsh is a scenic 145-acre nature park that includes a gazebo, walking paths, and two boardwalks that extend out into the marsh, so visitors can observe the wildlife. Stanfield Marsh is home to rare and diverse species of birds, fish, amphibians, and mammals. Rainfall and snowmelt are the only sources of water for Stanfield Marsh, so the water level varies from season to season. During wet periods, Stanfield Marsh is a thriving wildlife preserve. During extended drought conditions, the water level recedes dramatically, the boardwalks extend over dry soil, and presence of wildlife becomes scarce. In the last 15 years, Stanfield Marsh has been less than half full nearly 40 percent of the time.

4.2 Big Bear Lake

Stanfield Marsh is hydrologically connected to the Lake through a set of culverts under Stanfield Cutoff. The Lake is located about 6,743 feet (ft; 2,055 meters) above mean sea level (MSL) in the San Bernardino Mountains in San Bernardino County. Together, Stanfield Marsh and the Lake have a surface area of approximately 3,000 acres, a storage capacity of 73,320 AF, and an average depth of 32 ft. The Lake's sole source of water is currently snowmelt and stormwater runoff, which are highly variable. The Lake has several sources of water loss including evaporation, water extraction for snow making, dam releases for flood control, fishery protection, and water rights discharges.

The Lake was formed following construction of the Bear Valley Dam in 1883-1884 to serve as an irrigation supply for the citrus industry in the downstream Redlands-San Bernardino communities. BBMWD was formed in 1964 to manage and help stabilize the water level in the Lake. Historically, the Lake was operated as a storage reservoir by the Bear Valley Mutual Water Company (Mutual). However, due to the drastic fluctuations in Lake levels, legal negotiations arising from disagreement between Mutual, BBMWD, and the community of Big Bear Valley regarding water rights and management of the Lake, a 1977 Judgment was established. Under the terms of this court judgment, Mutual retains a storage right and ownership of all water inflow into the Lake. BBMWD is required to provide Mutual with up to 65,000 AF of water from the Lake in a 10-year rolling period.

In 1996, an In-Lieu Agreement was executed that allows BBMWD to maintain higher Lake levels by delivering water to Mutual from an alternate source of water. This alternate source of water, referred to as In-Lieu Water, comes mainly from the State Water Project (SWP) through the San Bernardino Valley Municipal Water District (SBVMWD), a State Water Contractor. Under the In-Lieu Agreement, when the Lake level falls more than 6 foot below full, and during some months when the Lake is between 4 and 6 feet below full, SBVMWD delivers SWP water to meet Mutual's needs instead of BBMWD releasing water from the Lake. BBMWD pays SBVMWD an annual fee that is adjusted each year based on property tax values.

Due to variable precipitation and extended drought, the Lake has experienced drastic changes in water levels, which impact its water quality. In December 2018, the Lake reached a historic low of 18'1" below full, which is less than 40% full by volume. **Figure 6** shows the fluctuation in Lake levels between 2000 and 2021.

The Lake is an important resource that provides extensive recreational, economic, ecological, and aesthetic benefits for the local community as well as the larger inland southern California region. The beneficial uses of the Lake and Marsh are presented in **Table 1**.

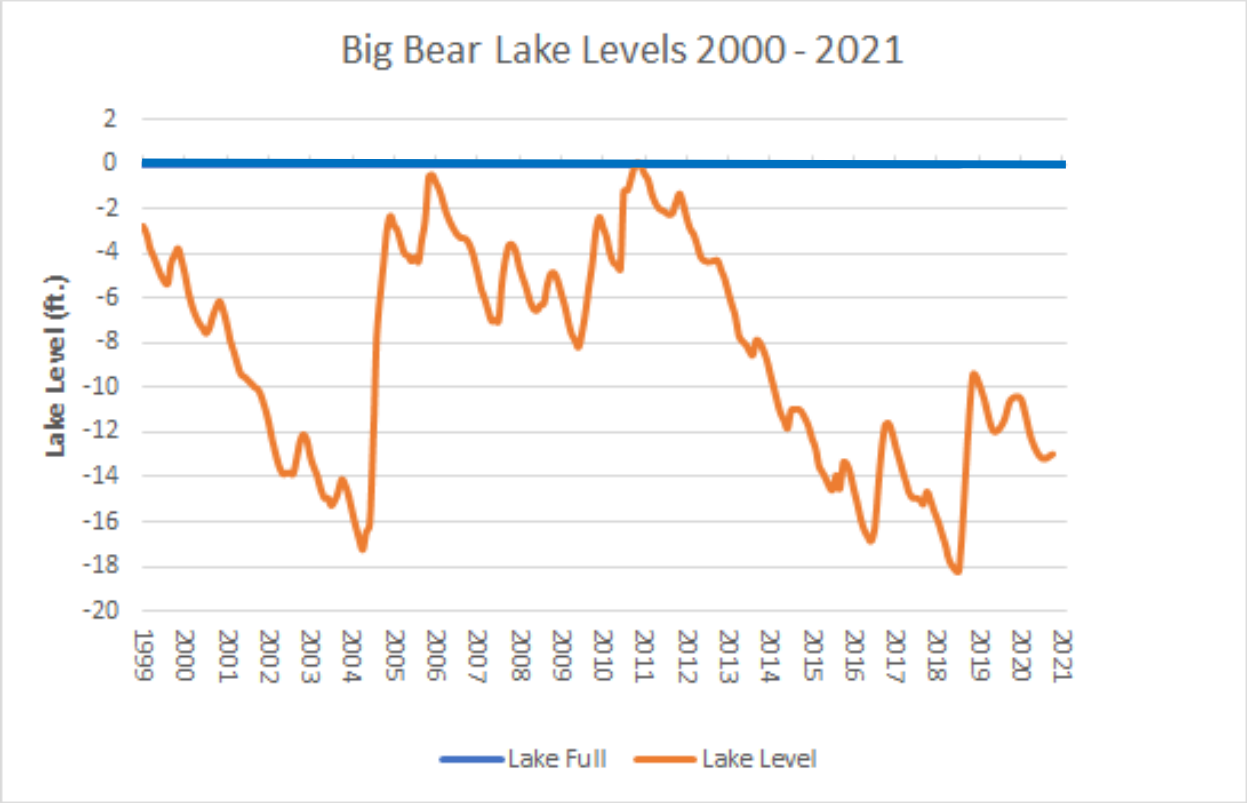

Figure 6. Big Bear Lake Levels: 2000 – 2021

4.3 Santa Ana Watershed

The Lake's dam releases are discharged to Bear Creek, a 17-mile stream, which enters the SAR at Reach 6. The Santa Ana River Watershed comprises portions of San Bernardino, Riverside, Los Angeles, and Orange Counties, covers an area of 2,840 square miles, and is home to over 6 million residents. The Santa Ana River is the major stream draining the watershed—about 100 miles in length from its headwaters near Big Bear to its discharge location in Huntington Beach. **Figure 7** shows the Santa Ana River Watershed, along with the Santa Ana River and its major tributaries.

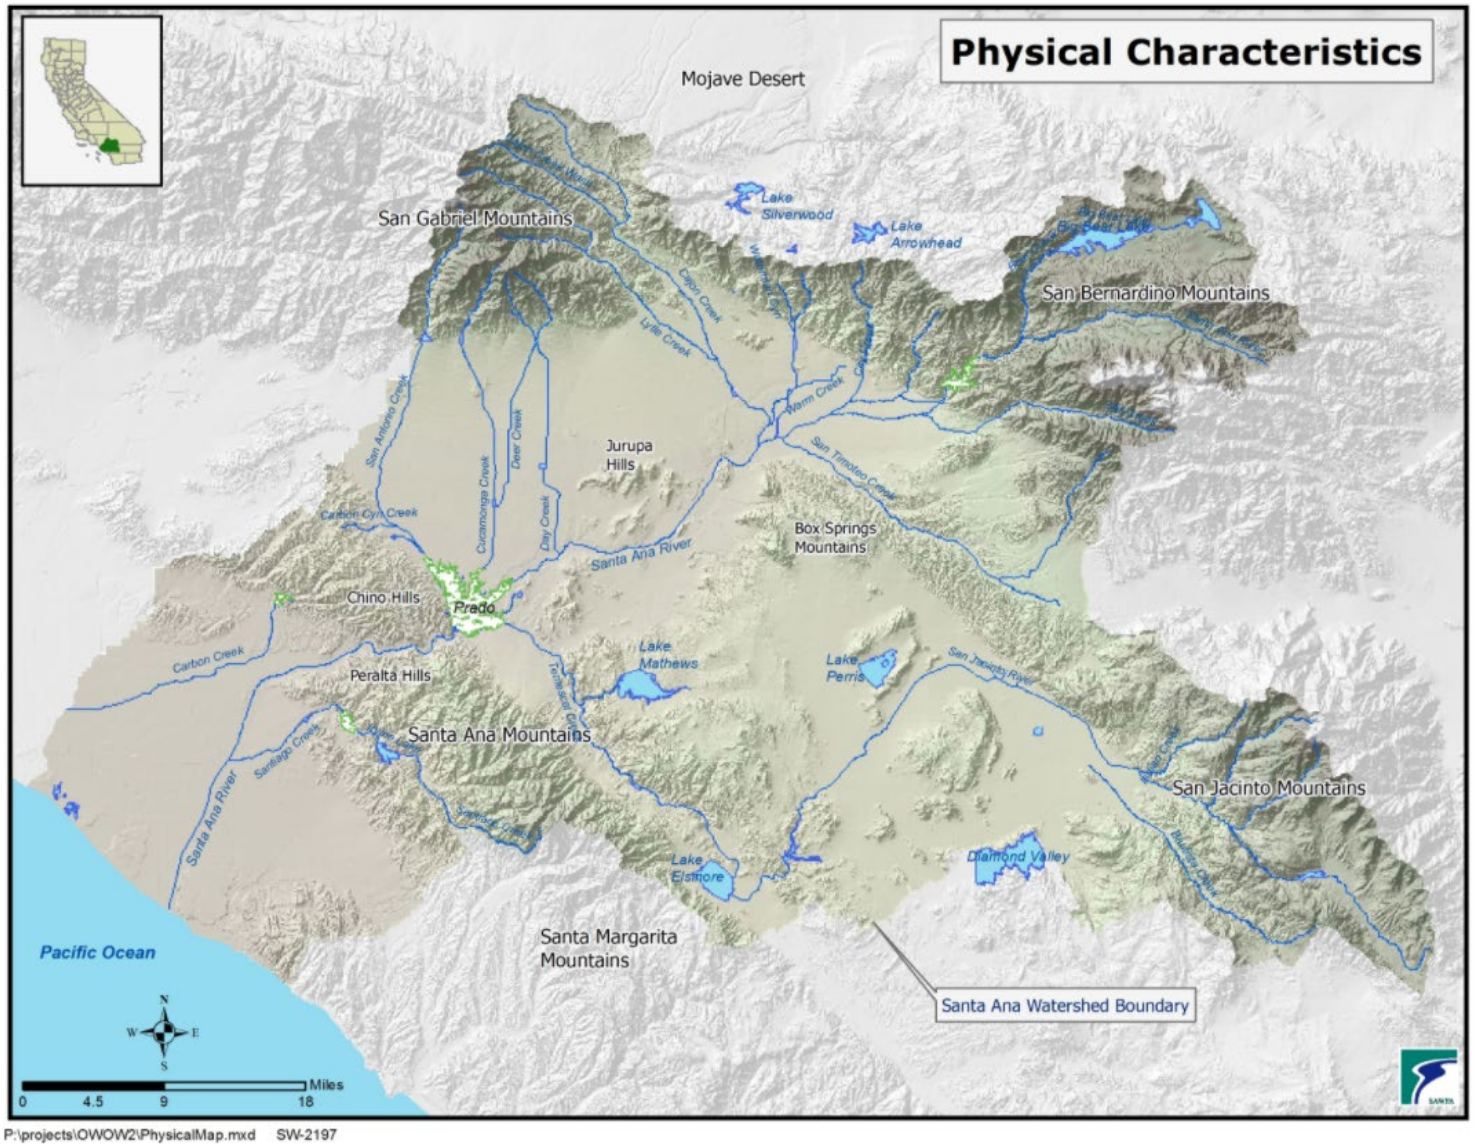

Figure 7. Santa Ana Watershed Map

5 ASSESSMENT OF WATER QUALITY IMPACTS TO BIG BEAR LAKE

This section summarizes the water quality assessment methodology and results for the proposed Lake discharge and potential associated impacts in downstream receiving waters.

5.1 Lake Discharge Project Description

As discussed in **Section 1**, one of the project components of the Replenish Big Bear Program is to discharge to the Lake disinfected, advanced treated effluent that has undergone RO and UV treatment. The Lake discharge is intended to help stabilize Lake levels especially during extended drought periods, assist to maintain the beneficial uses of the Lake, and reduce the in-lieu SWP water demands if higher lake levels allow for additional dam releases. The Lake has experienced record low levels over the last 15 years, forcing BBMWD to close one of their two boat ramps, which reduces the recreational benefit of the Lake.

The projected effluent quality of the proposed discharge is presented in **Table 5** for the constituents of interest in this study (constituents of interest are those listed in **Table 2**). Site-specific pilot testing of the proposed treatment process technologies will be completed in 2023 to establish design criteria and refine final effluent water quality estimates. The values presented in **Table 5** are based on mass balance calculations, vendor provided treatment performance estimates, and industry standard removal rates for RO treatment technology. The secondary effluent data were used as a basis for influent water quality to the advanced treatment train to estimate the projected effluent water quality for the proposed discharge.

Table 5. Projected Effluent Quality of Proposed Discharge and Existing Secondary Effluent Quality

Constituent	BBARWA Secondary Effluent Average Concentrations [a]	Projected Average Effluent Quality of Proposed Discharge	Unit
Ammonia as N	3.15	0.05	mg/L-N
Boron, Total	0.265	0.11	mg/L
Chloride	58	0.60	mg/L
Fluoride	0.41	<0.026[b]	mg/L
Hardness, Total (as CaCO3)	265	3.2	mg/L
Methylene Blue-Activated Substances	0.14	0.0014	mg/L
Sodium	NS	1.9	mg/L
Sulfate	41	0.20	mg/L
Total Dissolved Solids [c]	450	50	mg/L
Total Inorganic Nitrogen [c]	4.40	0.1	mg/L-N
Total Nitrogen [c]	7.80	0.6	mg/L-N
Chlorophyll-a [d]	N/A	N/A	µg/L
Total Phosphorus [c]	2.0	0.03	mg/L-P
Chlordane	<0.17 [e]	<0.17 [b][e]	µg/L
4,4'-DDT	<0.0052 [e]	<0.0052[b] [e]	µg/L
PCBs	<2.5 [e]	<2.5 [b] [e]	µg/L
Cadmium, Total	<0.11	<0.11[b]	µg/L
Copper, Total	14 [f]	0.07	µg/L
Lead, Total	1.3	0.01	µg/L
Mercury, Total	0.76 [g]	<0.5 [b]	ng/L
Aluminum, Total	180	1.3	µg/L
Specific Conductance	755 [e]	18	µmhos/cm

Notes: NS – Not sampled; N/A – Not applicable.

a) The average was estimated using detected values only, unless stated otherwise. NDs were not included due to the limited number of samples. This approach may result in higher averages.
b) The projected effluent quality is anticipated to be below the detection limit. The estimated projected concentration is shows as "<MDL".
c) Values were estimated as part of Draft Treatment Alternatives Analysis TM using BBARWA WWTP average effluent concentrations from weekly and monthly analyses for the 2017 - 2019 calendar years (WSC, 2020).
d) Chlorophyll-a is not a constituent that will be discharged by the BBARWA WWTP.
e) Based on one data point.
f) Values detected below the RL; reported concentration is estimated. Reported as "J-Flag."

Constituent	BBARWA Secondary Effluent Average Concentrations [a]	Projected Average Effluent Quality of Proposed Discharge	Unit
g) On June 18, 2020, BBARWA collected a sample to measure mercury using EPA Method 1631E, which has a reporting limit of 0.5 ng/L. This result is well below the 10 ng/L target described in the Statewide Mercury Control Program for Reservoirs.			

5.2 Selection of Water Quality Constituents

5.2.1 Selection Criteria

As presented in **Section 3**, water quality constituents assessed in this antidegradation analysis were identified based on one or more of the following conditions being satisfied:

1) Constituent has a WQO or criterion applicable to the Lake and/or downstream receiving waters;
2) Constituent for which an adopted TMDL exists;
3) Constituent identified as a pollutant/stressor on the 2018 CWA Section 303(d) list for the Lake or downstream of the proposed discharge; and
4) Constituent is a known water quality concern of the Regional Water Board.

Based on the conditions listed above, 22 constituents of interest were initially identified for evaluation and are presented in **Table 2.** The data available for the secondary effluent, proposed discharge effluent quality, and ambient water quality were assessed to determine the type of analysis needed for a given constituent. The following approach was used:

- No further analysis was needed for constituents reported as non-detect (ND) in the secondary effluent and the Lake. It is anticipated that RO treatment will achieve additional removal of these constituents and thus, will further reduce any water quality impacts potentially associated with these constituents.
- For constituents with detected concentrations in the secondary effluent, the proposed discharge water quality was compared to the ambient water quality and most stringent WQO or criterion.
- For the proposed discharge water quality constituents exceeding the ambient water quality or most stringent WQO or criterion, a mass balance analysis was completed.

- For constituents of greater interest to the Regional Water Board, such as TIN, TN, TP, and chlorophyll-a, the 2D hydrodynamic-water quality model (CE-QUAL-W2) developed by Dr. Anderson was used to evaluate the potential impacts of the proposed Lake discharge. A summary of the Lake Analysis (**Appendix B**) report along with the model updates recently completed to incorporate additional discharge volume scenarios and seasonal variability are presented in this report and in **Appendix C**.

5.2.2 Data Sources

Table 6 shows the water quality data used for the analysis. Per BBARWA's current WDR Permit, BBARWA is required to monitor for biological oxygen demand (BOD), total suspended solids (TSS), pH, dissolved oxygen (DO), TDS, sulfate, chloride, fluoride, nitrate as N, TN, E.coli, and volatile organic compounds (VOCs) in the secondary effluent on a monthly or annual basis. To support the preparation of the proposed project's Report of Waste Discharge (ROWD) and this analysis, water samples of the secondary effluent and Lake were collected and analyzed for priority pollutants. BBARWA collected its samples on November 18, 2021, and BBMWD collected the Lake samples on December 2, 2021. On June 18, 2020, BBARWA also collected a secondary effluent sample to measure mercury using EPA Method 1631E, which has a reporting limit of 0.5 ng/L. **Appendix D** contains the BBARWA, Lake, and Shay Pond (discussed in **Section 6**) water quality data.

As part of the Nutrient TMDL, a variety of constituents, including ammonia as N, total hardness, nitrate as N, nitrite as N, total kjeldahl nitrogen (TKN)[2], TP, and chlorophyll-a are collected at the four TMDL monitoring locations (Station 1 Dam, Station 2 Gilner Point, Station 6 Mid Lake Middle, and Station 9 Stanfield Middle. (See **Figure 2** in **Appendix B**). In the Lake Analysis, TIN[3], TN[4], TP, and chlorophyll-a were evaluated using the Nutrient TMDL data from 2009 through 2019. The average results calculated in the Lake Analysis are presented in **Table 6**.

Ammonia and hardness were not modeled in the Lake Analysis because these were not identified as constituents of interest at the time of the model development. For this analysis, the lake-wide annual average was estimated by averaging the four station annual averages consistent with the Nutrient TMDL approach, which consist of averaging the photic and bottom samples for each sampling date. From 2009 through 2019, about 1,280 and 1,180 data points were collected for ammonia and hardness, respectively, at these locations. The calculations are presented in **Appendix E**.

[2] TKN is the sum of organic nitrogen and ammonia.
[3] TIN is the sum of ammonia, nitrate, and nitrite.
[4] TN is defined as the sum of TKN, nitrite, and nitrate.

BBMWD also has manually recorded specific conductance data since 2001 measured at the first 10 to 15 feet below Lake surface. The specific conductance data was used to evaluate TDS in the Lake Analysis as specific conductance can be converted to TDS using a conversion factor that is dependent on the type of minerals and salts dissolved in the Lake. In August 2019, BBMWD collected TDS samples at the four TMDL monitoring locations to compare TDS and specific conductance results and calculated a conversion factor of 1 mg/L of TDS = 0.642 µmhos/cm, which was used in the Lake Analysis model. The Lake TDS average from this report was converted to µmhos/cm using this convention factor.

Table 6. Summary Statistics for Constituents Evaluated in Secondary Effluent and Big Bear Lake

Constituent	Unit	BBARWA Secondary Effluent [a]				Big Bear Lake[a]			
		No. of Samples	% Non-Detected	Avg.[b]	Max.	No. of Samples	% Non-Detected	Avg.[b]	Max.
Ammonia as N	mg/L	24	29%	3.15	22	1,281	33%	0.063 [c]	0.094
Boron, Total	mg/L	2	0%	0.265	0.270	1	0%	0.054 [d]	0.054 [d]
Chloride	mg/L	25	0%	58	63	1	0%	26	26
Fluoride	mg/L	2	0%	0.41	0.52	1	0%	0.41	0.41
Hardness, Total (as CaCO3)	mg/L	2	0%	265	270	1,176	0%	157 [c]	183
MBAS	mg/L	2	50%	0.14	0.14	1	0%	0.058 [d]	0.058 [d]
Sodium	mg/L	0	NS	NS	NS	1	0%	33	33
Sulfate	mg/L	20	0%	41	44	1	0%	18	18
Total Dissolved Solids	mg/L			450 [e]				251 [f]	
Total Inorganic Nitrogen	mg/L			4.40 [e]				0.049 [f]	
Total Nitrogen	mg/L			7.80 [e]				0.948 [f]	
Chlorophyll-a	µg/L			N/A				9.3 [f]	
Total Phosphorus	mg/L			2.00 [d]				0.037 [f]	
Chlordane	µg/L	1	100%	<0.17	<0.17	1	100%	<0.034	<0.034
4,4'-DDT	µg/L	1	100%	<0.0052	<0.0052	1	100%	<0.001	<0.001
PCBs (Aroclors) [g]	µg/L	1	100%	<2.5	<2.5	1	100%	<0.5	<0.5
Cadmium, Total	µg/L	8	100%	<0.11	<0.11	1	100%	<0.11	<0.11
Copper, Total	µg/L	8	88%	14 [d]	14 [d]	1	100%	<6.5	<6.5
Lead, Total	µg/L	8	75%	1.3	1.8 [d]	1	100%	1.8 [d]	1.8 [d]
Mercury, Total	ng/L	8	100%	0.76 [h]	0.76 [h]	2	50%	270	270
Aluminum, Total	µg/L	2	0	180	250	1	0%	58	58
Specific Conductance	µmhos/cm	1	0	755	755			391 [i]	

Notes: Bolded constituents were identified as constituents of interest by the Santa Ana Regional Water Board and were modeled in the Lake Analysis (**Appendix B** & **C**).

NS – Not sampled; N/A – Not applicable.

a) For constituents with only ND data, the method of detection limit (MDL) is shown as "<MDL."
b) The average was estimated using detected values only, unless stated otherwise. NDs were not included due to the limited number of samples. This approach may result in higher averages. For samples with only one data point, the reported value or "<MDL" is presented.
c) The averages and maximums are for the Lake-wide results and were calculated using Nutrient TMDL 2009-2019 data. See **Appendix E** – for estimates. ND were used and assumed to be "MDL/2".
d) Values detected below the RL; reported concentration is estimated. Reported as "J-Flag."
e) Values were estimated as part of Draft Treatment Alternatives Analysis TM using BBARWA WWTP average effluent concentrations from weekly and monthly analyses for the 2017 - 2019 calendar years (WSC, 2020).
f) TDS average was obtained from the Lake Analysis Table 19, and nutrients and chlorophyll-a from the Lake Analysis Table 22 (**Appendix B**).
g) PCBs are a class of chemicals which include Aroclors 1242, 1254, 1221, 1232, 1248, 1260, and 1016. The aquatic life criteria apply to the sum of the set of seven Aroclors. All results were non-detect.
h) On June 18, 2020, BBARWA collected a sample to measure mercury using EPA Method 1631E, which has a reporting limit of 0.5 ng/L. This result is well below the 10 ng/L target described in the Statewide Mercury Control Program for Reservoirs.
i) The Lake TDS average from the Lake Analysis report was converted to µmhos/cm using a 1 mg/L of TDS = 0.642 µmhos/cm conversion factor.

5.2.3 Selection of Constituents

The simple qualitative analysis described in **Section 5.2.1** was applied to the 22 constituents of interest to determine if additional analysis was required. **Table 7** shows the results of the comparison of the secondary effluent quality, projected effluent quality, ambient water quality, and the most stringent WQO or criterion.

Overall, no constituents exceeded their most stringent WQO or criterion and only boron and TIN exceeded existing, ambient water quality concentrations. For the remainder of the constituents—where the projected effluent quality is below the ambient water quality and the most stringent WQO or criterion—no additional analysis was conducted.

The Lake Analysis evaluated TDS, TIN, TN, TP, and chlorophyll-a, so potential TIN water quality impacts were addressed by the Lake Analysis. For boron, a simple mass balance spreadsheet model was used to evaluate the potential impacts of boron on the Lake with the proposed project due to the limited data available.

With respect to the three trace metals – cadmium, copper, and lead – included in the 2018 303(d) list for Reach 6 of the SAR as impairing the water body segment, projected average concentrations of the three trace metals in the proposed discharge are significantly below the hardness-based CTR chronic criterion calculated for each metal using a median total hardness value of 99 mg/L calculated for Reach 6 (see **Table 2**). Cadmium, copper, and lead concentrations contained in the disinfected, advanced treated effluent proposed for discharge to the Lake are not anticipated to lower water quality in Reach 6 for these trace metals, nor are they anticipated to affect future load or WLA included in an adopted TMDL.

Table 7. Comparison of Most Stringent Water Quality Objective or Criterion to Existing Ambient Lake Water Quality and Projected Effluent Quality of Proposed Discharge

Constituent	Unit	Most Stringent WQO or Criterion	Average Lake Concentration [a] [b]	Projected Average Effluent Quality of Proposed Discharge [c]	Comparison of Projected Effluent Quality to Most Stringent WQO (see table Notes)
Ammonia as N	mg/L	0.46	0.063 [d]	0.05	1
Boron, Total	mg/L	0.75	0.054 [e]	0.11	2
Chloride	mg/L	10	26 [e]	0.60	1
Fluoride	mg/L	0.9	0.41 [e]	<0.026	1
Hardness, Total (as CaCO3)	mg/L	125	157 [d]	3.2	1
MBAS	mg/L	0.05	0.058 [e]	0.0014	1
Sodium	mg/L	20	33 [e]	1.9	1
Sulfate	mg/L	10	18 €	0.20	1
Total Dissolved Solids	mg/L	175	251	50	3
Total Inorganic Nitrogen	mg/L	0.15	0.049	0.1	2,3
Total Nitrogen	mg/L	1	0.948	0.6	3
Chlorophyll-a	µg/L	14	9.3	N/A	3
Total Phosphorus	mg/L	0.035	0.037	0.03	3
Chlordane	µg/L	0.00057	<0.034 [e]	<0.17	4
4,4'-DDT	µg/L	0.00059	<0.001 [e]	<0.0052	4

Constituent	Unit	Most Stringent WQO or Criterion	Average Lake Concentration [a] [b]	Projected Average Effluent Quality of Proposed Discharge [c]	Comparison of Projected Effluent Quality to Most Stringent WQO (see table Notes)
Specific Conductance	µmhos/cm	700/1,000	391	18	1

Notes: Bolded constituents were identified as constituents of interest by the Regional Water Board and were modeled in the Lake Analysis (**Appendix B** & **C**).
N/A – Not applicable.

a) For constituents with only ND data, the method of detection limit (MDL) is shown as "<MDL."
b) The average was estimated using detected values only, unless stated otherwise. NDs were not included due to the limited number of samples. This approach may result in higher averages. For samples with only one data point, the reported value or "<MDL" is presented.
c) If the projected effluent quality is anticipated to be below the detection limit. The estimated projected concentration is shows as "<MDL".
d) The averages and maximums are for the Lake-wide results and were calculated using Nutrient TMDL 2009-2019 data. See **Appendix E** – for estimates. ND were used and assumed to be "MDL/2".
e) Average is based on one data point.

Blue – Projected effluent quality is below the ambient and most stringent WQO or criterion
Red – Projected effluent quality is above the ambient or most stringent WQO or criterion

1) Projected effluent quality is below the ambient and most stringent WQO or criterion. No degradation anticipated.
2) Projected effluent quality is above the ambient, but below the most stringent WQO or criterion. Further analysis needed to determine impacts on water quality.
3) Impacts evaluated in the Lake Analysis (**Appendix B & C**).
4) Secondary effluent and ambient water quality were ND. No further analysis conducted. It is anticipated that RO will achieve additional removal, resulting in even fewer impacts.

5.3 Water Quality Impacts Assessment

5.3.1 Lake Analysis Model Analysis Results

The Lake Analysis (**Appendix B**) was completed to evaluate the short- and long-term impacts of the Lake discharge on lake level, lake area, TDS, TIN, TN, TP, and chlorophyll-a under three different treatment alternatives:

- Alternative 1: TIN & TP Removal
- Alternative 2: 70% RO (in addition to TIN & TP Removal)
- Alternative 3: 100% RO (in addition to TIN & TP Removal)

These treatment alternatives were evaluated under three hydrologic conditions (i.e., extended drought (5th percentile), median (50th percentile), and prolonged above average rainfall (95th percentile)). The model predicted that Alternative 3 would result in a slight improvement in concentrations of TDS, TIN, TN, TP, and chlorophyll-a as compared to modeled baseline conditions. Informed by the results of this study, the 100% RO treatment alternative was selected as the preferred project and the projected effluent quality of Alternative 3 is the focus of this antidegradation analysis.

Additional refinements to the Lake Analysis were completed in 2022, as documented in **Appendix C**, to investigate the impacts of a higher discharge volume, account for WWTP discharge seasonal variability, and assess the impacts of a TP Offset Program as discussed in **Section 3.4** and Attachment B of the ROWD package. The 50th percentile hydrologic scenario for 2009-2050 was used in the updated analysis (i.e., the median hydrologic condition), as it includes a wide array of runoff conditions. All other hydrologic, meteorological, biological, chemical, and sedimentological factors, variables and conditions were identical to those used in prior simulations of long-term future conditions (Anderson, 2021).

The Lake Analysis report assumed a steady annual flow of 1,920 AFY of disinfected, advanced treated effluent discharged to the Lake that excludes the 80 AFY that could be discharged to Shay Pond. However, the proposed Lake discharge may be higher than previously modeled as it did not account for a 99% total recovery rate of BBARWA effluent and potentially a lower discharge rate to Shay Pond. **Table 8** presents the Lake discharge flow projections that were considered in the Lake Analysis model and in the 2022 update.

Table 8. Initial and Updated Lake Discharge Flow Rate Projections

Lake Analysis Modeled Scenario	RBB Inflow (AFY)	Daily RBB Inflow (MGD)
Baseline (No Project)	0	0
Alternative 3 [(a)]	1,920	1.71
High Flow (99% recovery) [(b)]	2,210	1.57 – 2.18
Mid Flow (90% recovery) [(b)]	2,009	1.42 – 1.98

Notes:

a) Alternative 3 was assessed in the 2021 Lake Analysis and assumed that of the total Replenish Big Bear effluent contribution considered in the Lake Analysis (i.e., 2,000 AFY), 80 AFY would be delivered to Shay Pond. Therefore, only 1,920 AFY would be discharged to the Lake.

b) In the 2022 Lake Analysis update it was assumed that no discharge to Shay Pond would occur and all disinfected, advanced treated effluent would be discharged to the Lake under two different total recovery rates scenarios.

The Lake discharge is expected to vary seasonally, as shown in **Figure 8**, and thus, differs from the earlier "Alternative 3" scenario that assumed a uniform flow rate of 1.71 MGD throughout the year. Inflows to the WWTP are lower in the summer months due to reduced inflow and fewer visitors relative to the winter season.

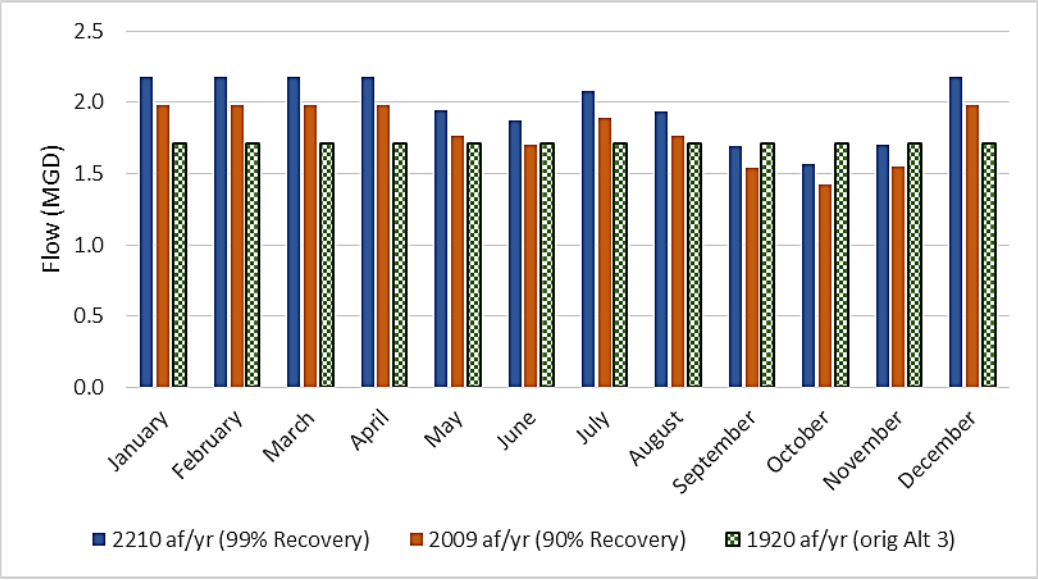

Figure 8. Projected 2040 Monthly BBARWA Discharges to the Lake under Three Inflow Scenarios

Since the Replenish Big Bear Program proposed Lake discharge has not been assigned a WLA for TP in the nutrient TMDL, a TP Offset Program is being proposed to attain a net zero TP contribution to be consistent with the Nutrient TMDL assumptions. A detailed analysis supporting the TP Offset Program is discussed in Attachment B of the ROWD package. In the Lake Analysis model update, the TP offset was modeled as equivalent to a 0 (zero) influent concentration. This approach is a simplification that may hold when considering a whole-lake nutrient budget. However, the Lake dynamics are complex, so projections may not have accounted for these complexities.

5.3.1.1 Lake Discharge Impacts Water Quality

The predicted long-term average water quality in the Lake under the updated modeled operational scenarios (increased and time-varying flows, with and without TP offset) are presented in **Table 9**. For comparison, the previously predicted baseline condition (no project) and Alternative 3 scenario are shown.

Table 9. Predicted Long-term Average Lake Concentrations for TDS, TIN, TN, TP, and Chlorophyll-a Under Different Operational Scenarios

Operational Scenario [a] (All at 50th %tile hydrologic condition)	TDS [b] (mg/L)	TIN [b] (mg/L)	TP [b] (µg/L)	TN [b] (mg/L)	Chlorophyll-a [c] (µg/L)
WQO/(TMDL target)	***175***	***0.15***	***0.15 (35.0)***		***(14.0)***
Baseline (No Project)	195	0.069	47.7	1.15	14.1
Alternative 3 (1920 AFY)	182	0.052	43.3	1.07	14.0
2,210 AFY (99% recovery)	179	0.045	42.3	1.04	13.1
2,009 AFY (90% recovery)	180	0.041	43.4	1.06	12.9
2,210 AFY + TP Offset	179	0.072	39.9	1.00	10.2
2,009 AFY + TP Offset	180	0.040	40.9	1.00	9.5

Notes:

a) The Baseline and Alternative 3 were evaluated in the 2021 Lake Analysis. The other operational scenarios were evaluated in the 2022 Lake Analysis Update and assume no discharge to Shay Pond. The TP Offset scenarios assume a TP Offset Program is implemented.
b) Expressed as annual average concentrations
c) Chlorophyll-a shown as growing season average concentrations

Overall, the predicted long-term average concentrations of TDS, TIN, TN, TP, and chlorophyll-a were lower with the proposed Lake discharge at various rates as compared to the predicted baseline condition, except for TIN under the 2,210 AFY + TP Offset. It is unclear why the model predicted increased TIN under this scenario while all other scenarios showed significantly reduced TIN values relative to the modeled baseline; however, the modeled difference in TIN between the Baseline and 2,210 AFY + TP Offset scenarios is approximately 4%, which is within the range of model variance and is considered statistically insignificant. Therefore, this analysis concludes that projected long-term average concentration of TIN is similar to the modeled baseline condition.

Focusing on chlorophyll-a as the key response target, baseline conditions were predicted to yield a growing season average chlorophyll-a concentration that slightly exceeded (by 0.1 µg/L) the Nutrient TMDL target value of 14 µg/L, while Alternative 3 matched the target value, and increased Lake discharges that varied seasonally (**Figure 8**) yielded values below the modeled baseline condition and the Nutrient TMDL target values. The assumption of a TP Offset Program yielded further reductions in chlorophyll-a. The increased Lake discharge volumes with reduced summer flows and no net TP loading were predicted to yield growing season average chlorophyll-a concentrations as low as 9.5 to 10.2 µg/L, significantly below predicted baseline and TMDL concentrations.

Cumulative distribution functions (CDFs) were prepared to evaluate the inter-annual differences in water quality, as differences are expected to persist. **Figure 9** shows the CDFs for TP, TN, and chlorophyll-a, which show that increased Lake discharges are predicted to lower the annual average TP and TN concentrations and growing season average chlorophyll-a concentrations. However, wide ranges in predicted concentrations remained in place. **Table 10** shows the predicted frequency of exceedance of the Nutrient TMDL targets or potential targets. Overall, the growing season chlorophyll-a average TMDL target (14 µg/L) was predicted to be exceeded about 53% of the time under baseline conditions and exceeded about 41% and 31% of the time at a 2,210 AFY Lake discharge rate with and without TP offset, respectively.

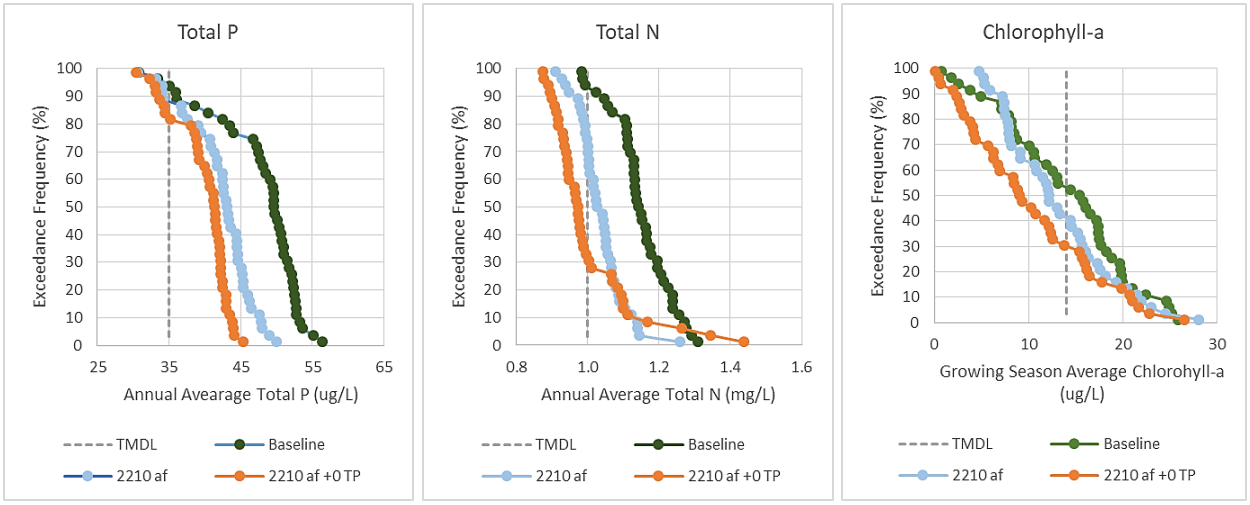

Figure 9. CDFs for Predicted Annual TP and TN Concentrations and Growing Season Average Chlorophyll-a Concentrations for Baseline Condition and at 2,210 AFY Lake Discharge with and without TP Offset

Table 10. Predicted Frequency of Exceeding TMDL Target Under Baseline Conditions and Different Lake Discharge Rates and TP Offset Scenarios (Annual Average or Growing Season Average Basis)

Operational Scenario (All at 50th %tile hydrologic condition)	TP (µg/L)	TN [a] (mg/L)	Chlorophyll-a [b] (µg/L)
WQO/(TMDL target)	***0.15 (35.0)***		***(14.0)***
Baseline (No Project)	94%	91%	53%
Alternative 3 (1920 AFY)	87%	72%	51%
2,210 AFY (99% recovery)	87%	72%	41%
2,009 AFY (90% recovery)	91%	80%	40%
2,210 AFY + TP Offset	82%	30%	31%
2,009 AFY + TP Offset	90%	55%	22%

Notes:
a) Possible target of 1 mg/L, per the Regional Water Board input.
b) Growing season is the period from May 1 through October 31 of each year.

In general, the Lake Analysis demonstrates that the Lake discharge will likely contribute to more frequent attainment of the Nutrient TMDL numeric targets and associated water quality standards, especially when combined with the offset program and actions taken by the TMDL responsible parties to attain the Nutrient TMDL requirements. Additionally, the Lake discharge will increase Lake levels, which will contribute to protection of other beneficial uses and reduce the amount of time critical hydrologic conditions occur in the Lake. A more robust analysis of this Lake discharge on the Nutrient TMDL is provided in Attachment B of the ROWD package.

5.3.1.2 Lake Discharge Impacts on Lake Level, Volume, and Area

The Lake Analysis simulations for the 2009-2019 evaluation period demonstrated that the Replenish Big Bear Program Lake discharge would result in significant increases in predicted lake levels, volumes, and surface areas relative to baseline conditions. Long-term (2009 to 2050) simulations of the proposed Lake discharge under three different hydrologic scenarios indicate that the discharge would be especially beneficial under an "extended drought" scenario where the discharge is predicted to increase the median lake level by more than 10 ft and the median lake area by nearly 600 acres, which in turn would improve recreational access and provide additional Lake habitat as compared to modeled baseline (no project) conditions. The increased lake level and area benefits provided by the Lake discharge would be more modest under the "prolonged above average rainfall" scenario because higher natural inflows would result in higher lake levels. **Table 11** summarizes the projected impacts on Lake level, area, and volume under three hydrologic conditions modeled in the 2021 Lake Analysis.

Table 11. Predicted Lake Level, Area, and Volume under Three Hydrologic Scenarios

Lake Physical Parameter (median values shown)	Scenario	Hydrologic Scenario		
		Extended Drought (5^{th} Percentile)	Median Hydrologic Condition (50^{th} Percentile)	Prolonged Above Average Rainfall (95^{th} Percentile)
Lake Level (ft) (Lake max 6,743 ft)	Baseline	6,722	6,733	6,736
	+Project	6,732 (+10.5)	6,738 (+7.2)	6,740 (+5.2)
Volume (AF)	Baseline	23,400	47,536	54,724
	+Project	45,750 (+22,340)	59,664 (+12,128)	65,204 (+10,480)
Area (acres)	Baseline	1,720	2,328	2,474
	+Project	2,290 (+572)	2,568 (+240)	2,669 (+195)
Notes: Data taken from Table 24 of Lake Analysis report. Assumed a discharge rate of 1,920 AFY. Additional benefit is expected with a higher discharge rate.				

5.3.2 Boron Mass Balance

The projected boron effluent quality of the proposed Lake discharge is anticipated to exceed the Lake ambient water quality (0.054 mg/L – based on one sample collected in December 2021) but remain well below the most stringent criterion of 0.75 mg/L for the protection of sensitive crops. Therefore, the Lake's boron assimilative capacity, defined as the difference between the criterion and the ambient water quality, is 0.694 mg/L (i.e., 0.75 mg/L – 0.054 mg/L).

Due to the limited amount of water quality data available, a simple spreadsheet model was completed to evaluate the contribution of the Lake discharge to boron concentrations in the Lake over time. The calculations are shown in **Appendix F**. The only available data for boron contributions to the Lake from natural inflows is based on boron samples collected in 1972 from several creeks. These data indicated that boron in natural inflows could range between 0.02 and 0.26 mg/L. These results were not used in this analysis due to it high variability, age of the samples, small sample size, and changes in watershed characteristics since the samples were collected.

This analysis did not establish a baseline condition based on ambient water quality; rather, it was assumed that the Lake and natural inflows had a boron concentration of 0 mg/L and the analysis determined the incremental increase of boron in the Lake as result of the Lake discharge.

The 1977-2020 annual inflow and outflow were obtained from the Big Bear Watermaster annual reports and a 43-year simulation was performed based on a repeat of this historic hydrology. The following equations were used to perform the mass balance:

$$Lake\ Storage\ =\ Initial\ Lake\ Storage\ +\ Lake\ Inflows\ -\ Lake\ Outflows$$

$$Lake\ Inflows\ =\ Lake\ inflows\ from\ precipitation\ and/or\ snowmelt$$

$$Lake\ Outflows\ =\ Spills\ +\ Releases\ +\ Leakage\ +\ Withdrawals\ +\ Evaporation$$

$$Boron\ Mass\ =\ Boron\ in\ Lake\ +\ Boron\ from\ Lake\ Inflow + Boron\ from\ Discharge\ -\ Boron\ from\ Lake\ Outflows$$

$$Boron\ Concentration\ in\ Lake\ (mg/L) = \frac{Boron\ mass\ in\ Lake\ at\ end\ of\ simulation\ year}{Lake\ volume\ at\ end\ of\ simulation\ year}$$

Figure 10 shows the projected boron Lake concentrations over the simulation period. The Lake discharge is anticipated to increase boron concentrations over the 44-year simulation, boron is predicted to increase by about 0.065 mg/L. This is less than the 10% assimilative capacity.

The projected incremental increase in boron concentration in the Lake as a result of the project is 0.065 mg/L at the end of the 44-year simulation. The simulation results represent an incremental increase above the current ambient quality, which was 0.054 mg/L based on one sample collected in December 2021. Based on this sample, the estimated total boron concentration in the Lake with the proposed discharge would be below 0.12 mg/L, which is considered safe for agricultural crops like citrus trees that show sensitivity to boron starting at concentrations between 0.5 – 0.75 mg/L (USDA, 1990). The projected boron concentration will remain low compared to the most stringent criterion of 0.75 mg/L which exists in the Basin Plan for the protection of water used to irrigate sensitive crops.

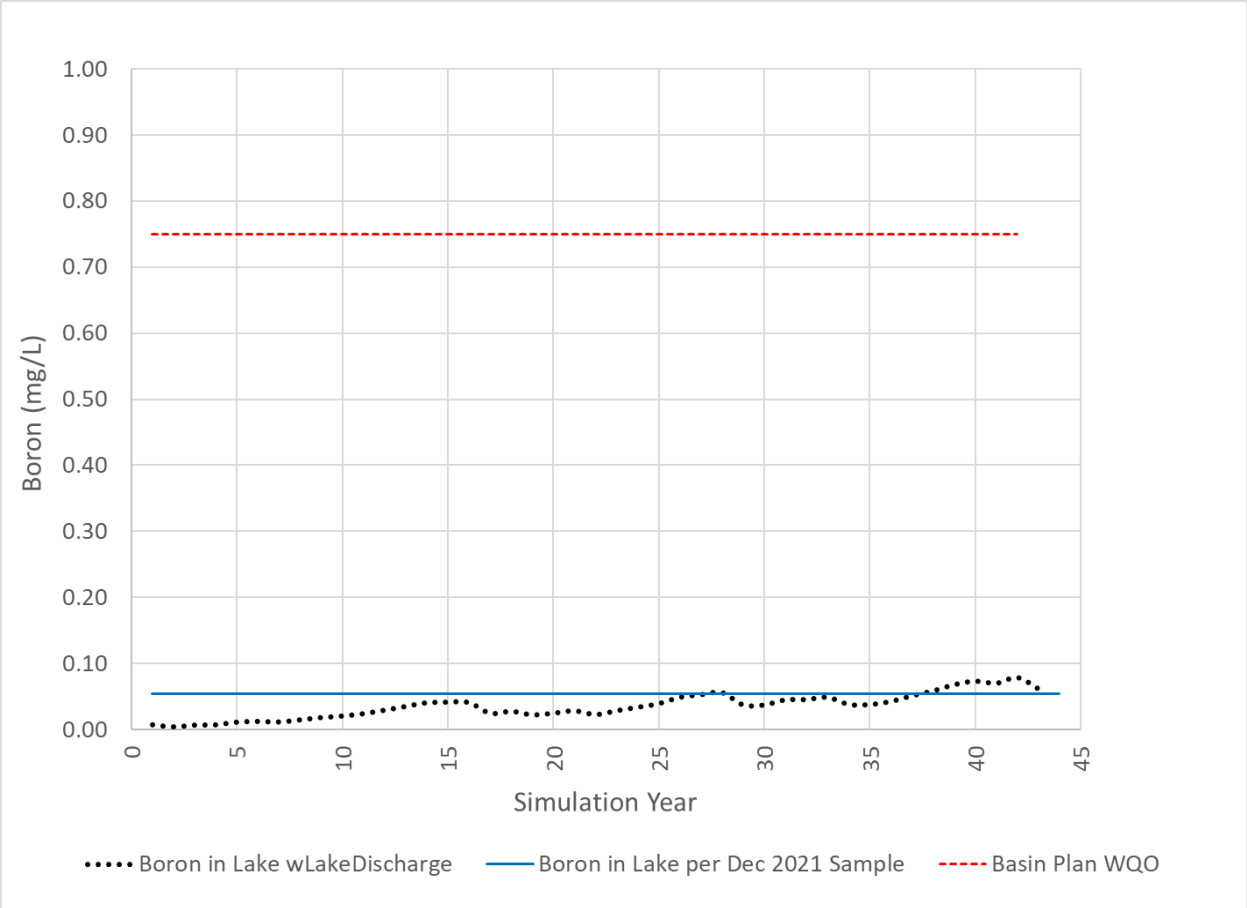

Figure 10. Projected Boron Concentrations with Proposed Lake Discharge

5.4 Summary of Water Quality Impacts

Overall, the Replenish Big Bear Program Lake discharge under most modeled discharge scenarios is anticipated to improve water quality for TDS, TIN, TP, TN, and chlorophyll-a as compared to baseline conditions, and result in similar water quality for total inorganic nitrogen (TIN) as compared to the modeled baseline. In addition, the proposed discharge is projected to contain concentrations of constituents of interest that are similar to or lower than existing ambient water quality and most stringent WQO or criteria for all constituents evaluated except for TIN and boron. For boron, concentrations in the Lake are anticipated to increase compared to baseline conditions but remain well below the most stringent WQO of 0.75 mg/L and the estimated increase is below the U.S. EPA significance threshold of a 10% reduction in available assimilative capacity.

Overall, the Lake Analysis and the 2022 Lake Model Update show that the implementation of the Lake discharge will help improve water quality of the Lake, especially during extended drought and typical (median) conditions. In addition, the proposed Lake discharge will increase lake levels, surface area, and volumes which will help to protect the beneficial uses designated for the Lake.

6 ASSESSMENT OF WATER QUALITY IMPACTS TO SHAY POND

This section describes the proposed Shay Pond discharge component of the Replenish Big Bear Program and presents an antidegradation analysis of the proposed discharge. Currently, it is unknown if Shay Pond and Shay Creek are considered Waters of the U.S. (WOTUS), as the federal regulations that define a WOTUS are currently under review. Regional Water Board input is required to determine the appropriate permitting approach for the proposed discharge to Shay Pond. The necesarry background information to assist the Regional Water Board with this determination is provided in this section.

6.1 Shay Pond Environmental Setting and Project Description

As part of the Replenish Big Bear Program, up to 80 AFY of disinfected, advanced treated effluent is proposed for discharge to Shay Pond. The proposed Shay Pond discharge is intended to replace potable water that is currently discharged to the pond to support the Unarmored Threespine Stickleback (Stickleback) fish, a federal and State listed endangered species.

Shay Pond has a surface area of approximately 10 acres and is located about 1.2 miles southeast of the BBARWA WWTP (**Figure 1**). According to the Bear Valley Basin Groundwater Sustainability Plan (GSP), "*Shay Pond is a natural surface water body at the southern base of an unnamed ridge that separates it from Baldwin Lake (. The nature of this pond is unknown, but it may be fed, in part, from spring flow, surface runoff, and periodically, groundwater intersecting the land surface. Although the pond may have historically been fed from surface water runoff in the ephemeral, upstream segment of Shay Creek, urban development has altered the course of this stream, and it no longer flows into the pond. Surface water exits Shay Pond via the downstream segment of Shay Creek, which flows northwards toward Baldwin Lake and intermittently provides water to Baldwin Lake lake.*" "*Surface water sources to Baldwin Lake are primarily in the form of ephemeral streams with relatively low flow volumes. The only stream where surface water flow periodically has been measured is Shay Creek at its outlet from Shay Pond.*" "*Surface water runoff does not reach Baldwin Lake during most years but percolates into the groundwater system. However, during prolonged precipitation, surface water does flow into Baldwin Lake. All surface water that enters Baldwin Lake is lost to evaporation. The high clay content of the playa sediments prevents vertical migration, and the topographical configuration of the lake prevents outflow from Baldwin Lake*" (TH&Co, 2022). **Figure 11** shows how

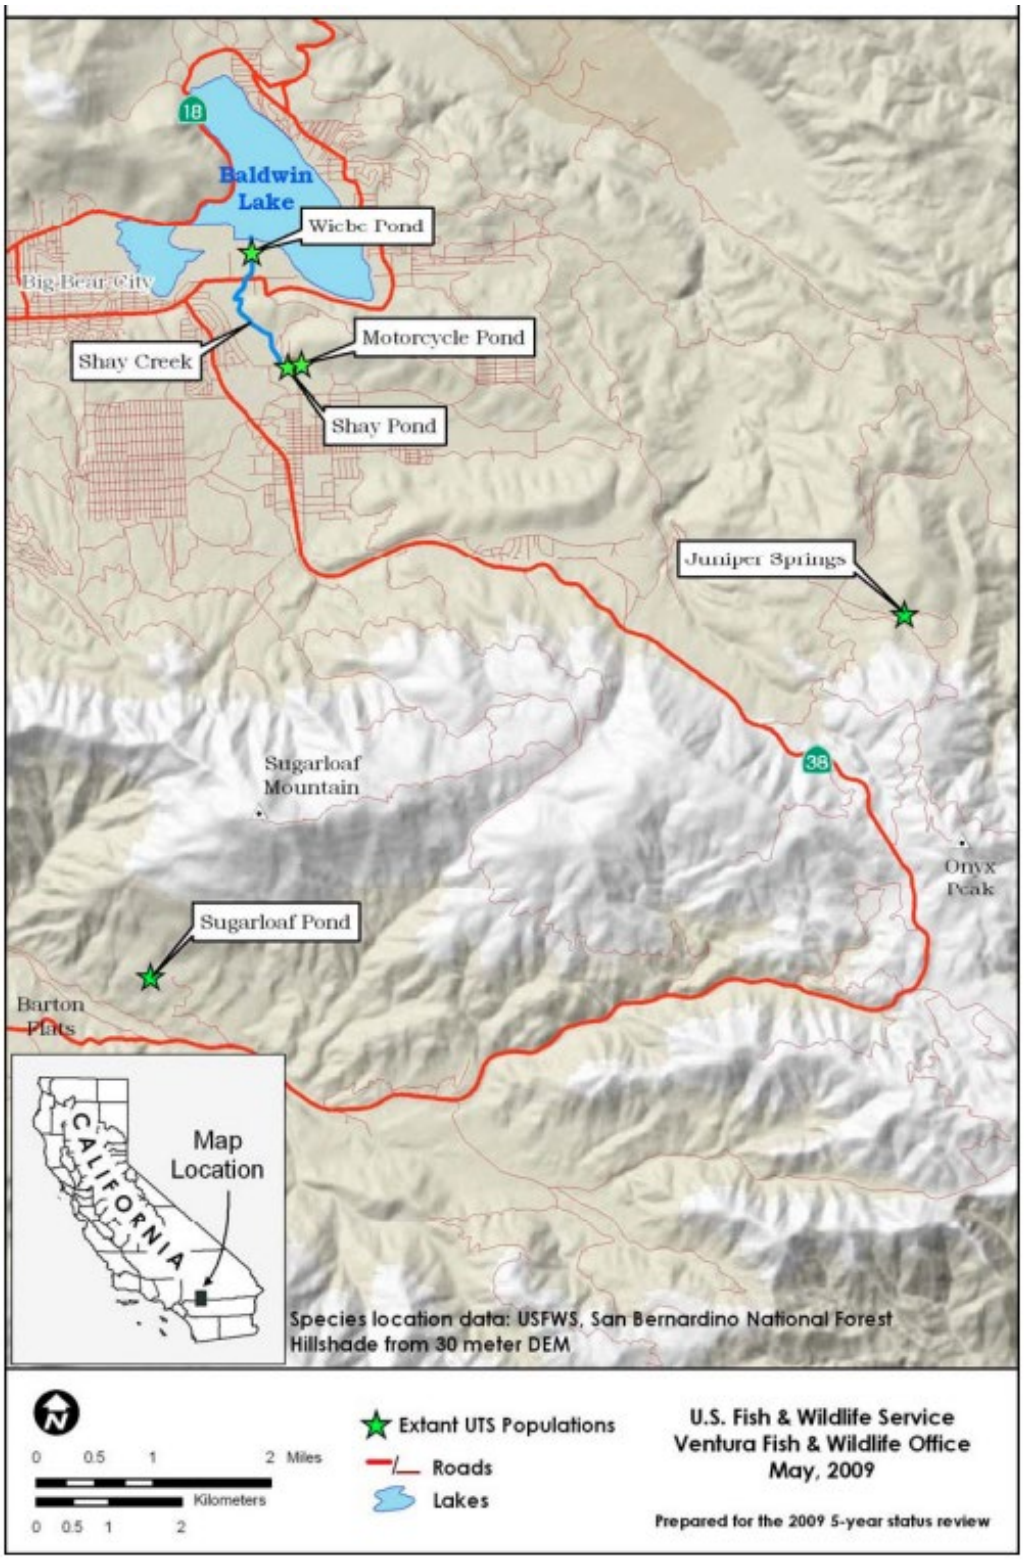
Baldwin Lake, an ephemeral lake, is connected to Shay Pond via Shay Creek. This figure also shows the population of Stickleback fish in the vicinity of Shay Pond.

The population of Stickleback is unique in that it occurs at a high elevation, about 6,700 ft above mean sea level, while all other Stickleback populations inhabit streams below 3,000 ft. In 1985 and 1986, catastrophic mortality of Stickleback in the Valley occurred due to insufficient amounts of water. By the summer of 1990, it was thought that the Stickleback remained in only Shay Pond.

There is a long history of study and group effort regarding the Stickleback in the Shay Creek area. The main stakeholders include the United States Fish and Wildlife Service (USFWS), CDFW, the San Bernardino National Forest (SBNF), BBCCSD, BBLDWP, and BBARWA. Additionally, the Shay Creek Working Group, which includes representatives from the USFWS, CDFW, SBNF, BBCCSD, BBLDWP, and BBARWA, was formed during the process of preparing the USFWS' 2002 Biological Opinion (2002 BO) for the area (Evans, 2002).

The requirements of the 2002 BO state that BBCCSD will provide water to Shay Pond to maintain a minimum 20-gallon-per-minute outflow from Shay Pond. The objective is to maintain a minimum pond water level that will support suitable habitat conditions for the fish. BBCCSD currently meets this requirement by discharging potable water into Shay Pond, but the 2002 BO also states that, should a suitable alternative supply of water be found to be appropriate for the stickleback in the future, BBCCSD may use an 'in-lieu' water supply, which could include the use of tertiary-treated water. The potable water discharged to Shay Pond represents approximately 5% of BBCCSD's customer water demand and could be reserved for potable use instead of discharging to Shay Pond.

The discharge rate needed to maintain the required outflow, accounting for evaoparation and infiltration, has varied from year to year. However, based on the average volume of discharges measured between 2012 and 2020, BBCCSD discharges approximately 50 AFY of potable water to Shay Pond on average. At times, the required discharge has been up to 80 AFY; this maximum volume is used as the basis for the project design and analysis to be conservative. **Figure 12** shows an aerial view of Shay Pond and the proposed discharge location.



(Source: USFWS, 2009)

Figure 12. Shay Pond Aerial View

6.2 Applicable Water Quality Standards

Per the Basin Plan, the protection of beneficial uses designated for Shay Creek and Baldwin Lake is primarily provided by narrative water quality objectives. **Table 12** shows the designated beneficial uses of Shay Creek and Baldwin Lake, which are receiving waters for flows from Shay Pond. Baldwin Lake has intermittent beneficial uses as the lake is ephemeral. The water quality objectives used to protect the beneficial uses designated for Shay Creek and, therefore, Shay Pond are presented in **Table 13**, along with ambient Shay Pond water quality, the quality of the current potable water supply to the pond, and the proposed effluent quality of the proposed discharge.

Table 12. Beneficial Uses of Shay Pond Receiving Waters

Beneficial Uses	Shay Creek	Baldwin Lake
COLD – Cold Freshwater Habitat	✓	I
GWR – Groundwater Recharge	✓	
MUN – Municipal and Domestic Supply	✓	I

Beneficial Uses	Shay Creek	Baldwin Lake
RARE – Rare, Threatened, or Endangered Species	✓	I
REC1 – Water Contact Recreation	✓	I
REC2 – Non-Contact Water Recreation	✓	I
SPWN – Spawning, Reproduction, and/or Early Development	✓	
WARM – Warm Freshwater Habitat		I
WILD – Wildlife Habitat	✓	I
Notes: ✓ - Existing or Potential Beneficial Use; I - Intermittent Beneficial Use		

6.3 Assessment of Water Quality Impacts

The water quality data available for Shay Pond are limited, so a detailed water quality assessment using Shay Pond data could not be completed. For this analysis, the existing water quality of potable water supplies near Shay Pond were compared to the projected effluent quality of the proposed Shay Pond discharge to determine if there is a potential for degradation of Shay Pond water quality as a result of the proposed discharge. The water quality collected in Shay Pond as part of the ROWD application is provided as reference. A similar approach as outlined in **Section 5.2.1** was used to determine if the proposed discharge to Shay Pond could contribute to ambient water quality degradation. **Table 13** presents the results of this analysis.

Water quality data for the specific well that discharges to Shay Pond is not available so the data used for this analysis was obtained by compiling and averaging the water quality data from seven drinking water wells near Shay Pond, which is expected to be representative of the quality of groundwater currently discharged to Shay Pond. BBCCSD collected these data in 2020. The projected effluent quality was estimated as described in **Section 5.1** and presented in **Table 5.** As part of the ROWD process, BBCCSD sampled Shay Pond for 156 constituents, of which only 19 analytes were detected.

Overall, the projected effluent quality of the proposed discharge to Shay Pond is better than the current potable water supply for chloride, hardness, sodium, sulfate, TDS, TN, aluminum, and specific conductance. The projected effluent quality of the proposed discharge is expected to be of similar quality as existing potable water supplies for ammonia, fluoride, MBAS, cadmium, copper, and lead. However, additional data may be needed to confirm these findings. Boron may be the only constituent that could be above the existing potable water supply quality. However, the average boron concentration in the disinfected, advanced treated effluent proposed for discharge to the pond is well below the 0.75 mg/L Basin Plan objective for boron for the protection of sensitive agricultural crops, which is not a use of Shay Pond water.

Additional coordination with the CDFW will be conducted to ensure the Stickleback fish are protected.

Table 13. Comparison of Most Stringent Water Quality Objective or Criterion to Current BBCCSD Potable Water Supply Quality and Projected Effluent Quality of Proposed Discharge

Constituent	Units	Reference for Most Stringent WQO or Criterion	Average Quality of Potable Groundwater Supply [a]	Shay Pond Ambient Quality [b]	Projected Effluent Quality of Proposed Discharge	Comparison of Projected Effluent Quality to Most Stringent WQO (See Table Notes)
Ammonia as N	mg/L	1.4 [c]	NS	0.24	0.05	1
Boron	mg/L	0.75	<0.1	0.059	0.11	2
Chloride	mg/L	500	9	7.6	0.60	1
Fluoride	mg/L	0.9	2.1	1.2	<0.026	1
Hardness, Total (as CaCO3)	mg/L	100	209	180	3.2	1
MBAS	mg/L	0.05	<0.1	<0.1	0.0014	1
Sulfate	mg/L	500	39	23	0.20	1
Total Dissolved Solids	mg/L	1000	291	320	50	1
Total Nitrogen	mg/L-N	10	NS	1.2	0.60	1
Cadmium	µg/L	1.5 [d]	<1	<1	<0.11	1
Copper	µg/L	16.6 [d]	<50	<50	0.07	1
Lead	µg/L	3.5 [d]	<5	<5	0.01	1
Aluminum	µg/L	200	<50	120	1.3	1
Specific Conductance	µmhos/cm	700/1000	496	450	18	1

Notes: NS – Not sampled/no data

a) The average groundwater potable water supply was estimated from 7 domestic wells that were tested and are near Shay Pond. NDs were excluded from the average. Constituents with all ND are reported as "<RL." The MDL was not provided.
b) For Shay Pond, only one sample is available. The results are reported. ND are reported as "<MDL."
c) The total ammonia was estimated using the equation presented in Table 4-4 of the Basin Plan. The field temperature on November 17, 2021, was 56 °F (13.3°C) and pH was 7.7.
d) The cadmium, copper, and lead SSO were estimated using a total hardness value of 180 mg/L, based on the sample collected as Shay Pond.

Constituent	Units	Reference for Most Stringent WQO or Criterion	Average Quality of Potable Groundwater Supply [a]	Shay Pond Ambient Quality [b]	Projected Effluent Quality of Proposed Discharge	Comparison of Projected Effluent Quality to Most Stringent WQO (See Table Notes)

Blue – Projected effluent quality is below the ambient and most stringent WQO or criterion
Red – Projected effluent quality is above the ambient or most stringent WQO or criterion

1) Projected effluent quality is below the ambient and most stringent WQO or criterion. No degradation anticipated.
2) Projected effluent quality is above the ambient, but below the most stringent WQO or criterion. Further analysis needed to determine impacts on water quality.

7 EVALUATION OF CONSISTENCY WITH ANTIDEGRADATION POLICY

The guidelines set by the State Water Board for the antidegradation analysis (APU 90-004) provide direction on evaluating the proposed discharges to Stanfield Marsh/ Lake and Shay Pond by focusing on whether and the degree that water quality is lowered, and by considering whether or not the assumed water quality discharge is consistent with the maximum benefit to the people of the State. In developing the antidegradation analysis, the beneficial uses and relevant water quality objectives and commonly used criteria for the Lake and Shay Pond were considered.

7.1 Benefits of Proposed Project

The proposed discharges of disinfected, advanced treated wastewater to Stanfield Marsh and Shay Pond maximize the use of a local sustainable water supply within the Valley region through the surface water discharge of highly treated wastewater produced by BBARWA to directly benefit the community and environment and support the following beneficial uses in the Lake, Stanfield Marsh, and Shay Pond: AGR (Lake only), COLD, GWR (Lake and Pond), MUN, RARE, REC1, REC2, SPWN (Lake and Pond), WARM (Lake and Pond), and WILD (see **Table 1** and **Table 12** for additional details). The proposed Lake and Shay Pond discharges as part of the Replenish Big Bear Program are anticipated to provide the following benefits:

- A new local drought proof water supply will reduce the Valley's vulnerability to drought, both for the community and the environment.
- A new constant source of water supply to Stanfield Marsh that will provide more stable aquatic and riparian habitat for diverse species and more opportunities for the community to realize the educational and recreational benefits of Stanfield Marsh. The marsh has been mostly dry since 2015 but with the project, the 145-acre marsh area will be at least 50% wetted even during dry years.
- Increased Lake levels will provide more wetted shoreline to enhance aquatic and riparian habitat in the Lake.
- Increased lake levels provide increased opportunities and flexibility for BBMWD to conduct lake management activities, such as weed harvesting to control aquatic macrophytes. Such activities are anticipated to enhance the contact and non-contact recreation in the Lake.

- Increased Lake levels will improve Lake access for boats and personal watercraft and allow for continued use of Lake water for snowmaking in the winter, both of which will act to maintain and enhance tourism, the single largest driver of the Big Bear economy.
    - The number of boat permits sold is directly impacted by Lake levels, and it is anticipated that increased levels will result in the sale of additional boat permits and increased rates of associated recreation and tourism, all of which stimulate the local and regional economies.
    - Visitors in the winter are directly tied to weather conditions and the Resorts' ability to facilitate snow activities by extracting Lake water to make snow when Lake levels are high enough.
    - The Transient Occupancy Tax (TOT) is the second largest revenue source for the City of Big Bear Lake, making up approximately 27% of the general-purpose revenues. Revenue from tourists fluctuate depending on the timing and amount of precipitation the region receives and Lake levels.
    - A strengthened tourist economy is expected to provide additional job growth and stability. Project implementation is estimated to create 3 new permanent positions at the WWTP, 242 temporary construction jobs and 480 indirect jobs.
- Higher Lake levels will result in reduced demand on SWP water, which is used in lieu of Lake water to meet Mutual's water needs when Lake levels are low.
- Increased inflow to the Lake will result in the Lake being full more frequently and will provide BBMWD additional flexibility in optimizing Lake releases to provide new downstream benefits to the Santa Ana Watershed, including increased flows in Bear Creek and the Santa Ana River to support habitat and additional downstream capture of surface water for groundwater recharge.
- The Lake discharge provides opportunities to use of a portion of the Lake water for subsequent uses that provide additional potable water supply and recreational benefits through direct and in-lieu groundwater recharge and enhanced snowmaking capabilities (these uses are anticipated to be permitted separately).

- A new source of high-quality water will be discharged to Shay Pond to support 10 acres of habitat for the federally listed Stickleback. The new source of water enables the potable water currently used for this purpose to be stored in the groundwater basin to enhance water supply sustainability.

7.2 Socioeconomic Considerations

As a result of the project benefits described in **Section 7.1**, the proposed project will act to support important economic and social development in the Valley.

The project proponents are voluntarily committing the resources necessary to construct and operate an advanced wastewater treatment facility to discharge disinfected, RO treated effluent of the quality that could be permitted to be discharged to the Lake as a means to achieve the multiple project benefits described above. The commitment of resources by the project proponents to construct, operate, and maintain the proposed treatment facility will result in increased wastewater fees paid by residents and businesses in the Valley. The capital cost of the proposed facilities required for the Lake and Shay Pond discharges is estimated at $56 M (in 2021 dollars) and the annual operations and maintenance (O&M) costs are estimated at $2.4 M (in 2021 dollars). These capital and O&M expenditures are estimated to result in an increase in wastewater fees of approximately $150-$200 per connection per year.

Increased wastewater fees that would be paid by residents and businesses in the Valley with implementation of the proposed project are not without local and regional economic impacts. The estimated increase in wastewater fees would need to be paid by households and businesses out of their existing household incomes or operations budgets, respectively. In effect, additional wastewater fees would be paid out of funds that are currently available for other purposes. With respect to households, future increased wastewater fees would result in less disposable personal income available to a household for the purchase of other goods and services. Similarly, an increase in annual utility costs for a business could result in one or more of the following: increased costs for the goods and/or services it provides and/or decreased reinvestment in the business. With respect to individual households, increases in utility costs have a disproportionate effect on households at the lowest socioeconomic levels.

While the estimated increase in annual wastewater fees with implementation of the proposed project is not estimated to produce substantial and widespread economic impacts in the Valley, a requirement to add additional wastewater treatment beyond the advanced level of treatment included in the proposed project could trigger substantial and widespread socioeconomic impacts. Furthermore, the project proponents believe that the cost of any additional required wastewater treatment would not produce improvements in receiving

water quality that are proportionate with the cost of additional treatment. The benefits of maintaining existing water quality and mass emissions in the Lake and Shay Pond for the constituents analyzed in this antidegradation analysis are not commensurate with the costs of additional wastewater treatment, beyond what is included in the proposed project, should such treatment be recommended. The small decrease in water quality with respect to the constituents considered in this analysis is unlikely to affect beneficial uses of the Lake, Shay Pond, and downstream receiving waters.

7.3 Consistency with Antidegradation Policies

The proposed project, the discharge of disinfected, advanced treated BBARWA effluent to (1) Stanfield Marsh/Big Bear Lake at a discharge rate up to 2,210 AFY and (2) Shay Pond at a discharge rate up to 80 AFY, is determined to comprise best practicable treatment and control and is consistent with federal and State antidegradation policies for the following reasons:

- The proposed discharge to both Stanfield Marsh/Big Bear Lake and Shay Pond will not adversely affect existing or probable beneficial uses of either receiving water or downstream receiving waters, nor will the discharges cause water quality to not meet applicable water quality objectives.
- Overall, the proposed discharge is estimated to improve water quality in the Lake for TDS, TN, TP, and chlorophyll-a, maintain similar water quality for TIN, and have a very minor impact on boron. Future boron concentrations in the Lake are estimated to increase very slightly (i.e., less than 10% of the available assimilative capacity) due to the proposed BBARWA discharge but are estimated to remain well below the 0.75 mg/L Basin Plan objective for boron (see **Table 7** and **Section 5.3.2**). The Lake Analysis shows that projected ambient Lake concentrations of TIN and chlorophyll-a with the proposed discharge will exist below their relevant water quality objective (TIN) or TMDL target (chlorophyll-a). The Lake Analysis also shows that ambient Lake concentration of TDS and TP with the proposed discharge are estimated to exceed the 175 mg/L TDS objective and the 35 µg/L TP TMDL target, respectively. However, the modeled baseline (no project) condition is projected to result in Lake concentrations for TDS, TP, TIN, and chlorophyll-a that exceed those concentrations more often than all modeled BBARWA discharge scenarios. Modeled results for the proposed BBARWA discharge, when combined with a TP Offset Program (see Attachment B of the ROWD package), show the greatest improvements to future, ambient Lake concentrations as compared to the modeled baseline (no project) condition.

- Overall, the proposed BBARWA discharge is estimated to have a very minor impact on Shay Pond water quality and Shay Creek water quality downstream of the pond. The proposed project is estimated to potentially cause a very minor increase in boron concentrations in the pond and downstream in Shay Creek, but concentrations are estimated to remain well below the 0.75 mg/L Basin Plan objective for boron. The disinfected, advanced treated effluent proposed for discharge to the pond is anticipated to lower the concentrations of those constituents listed in **Table 13** as compared to existing ambient concentrations that are largely influenced by the groundwater currently discharged by BBCCSD to the pond to maintain water levels for the endangered Stickleback fish.
- Based on the above, the request to permit a new discharge to both Stanfield Marsh/Big Bear Lake and Shay Pond is consistent with federal and state antidegradation policies in that the minor lowering of water quality for boron in Big Bear Lake (see **Table 7**) and Shay Pond (see **Table 13**) is necessary to accommodate important economic or social development[5], will not unreasonably affect beneficial uses, will not cause further exceedances of applicable water quality objectives, and is consistent with the maximum benefit to the people of the State.
- Based on the above, the request to permit new discharges to Stanfield Marsh/Big Bear Lake and Shay Pond are consistent with the Porter-Cologne Act in that the resulting water quality will constitute the highest water quality that is reasonable, considering all demands placed on the waters, economic and social considerations, and other public interest factors.

The proposed discharge of disinfected, advanced treated BBARWA effluent to Stanfield Marsh/Big Bear Lake and Shay Pond also fully supports California's *Recycled Water Policy* (SWRCB, 2013) in that it would result in an increased use of recycled water from municipal wastewater sources, would incrementally reduce reliance on the vagaries of annual precipitation, and would assist in the sustainable management of surface and groundwater resources.

[5] Maintain and improve recreation and tourism in the Big Bear Lake region which in turn stimulates the local and regional economies.

CALIFORNIA REGIONAL WATER QUALITY CONTROL BOARD
COLORADO RIVER BASIN REGION

ORDER R7-2021-0023

WASTE DISCHARGE REQUIREMENTS
FOR
BIG BEAR AREA REGIONAL WASTEWATER AGENCY, OWNER/OPERATOR
EXPORT OF RECYCLED WATER TO LUCERNE VALLEY
LUCERNE VALLEY-SAN BERNARDINO COUNTY

The California Regional Water Quality Control Board, Colorado River Basin Region (Regional Water Board) hereby makes the following Findings:

1. Big Bear Area Regional Wastewater Agency (BBARWA or Discharger), P.O. Box 517, Big Bear City, California 92314, owns 480 acres in the Lucerne Valley, of which 340 acres are irrigated with recycled water from the Discharger's Wastewater Treatment Plant (WWTP). There are an additional 140 acres available for irrigation, also in the Lucerne Valley. BBARWA's WWTP provides sewerage service to the City of Big Bear Lake, Big Bear City Community Services District, and County Service Area 53-B. The WWTP is located at 122 Palomino Drive, Big Bear City, California 92314, and has a design treatment capacity of 4.89 million gallons-per-day (MGD) and a hydraulic capacity of 9.2 MGD. The Facility is assigned California Integrated Water Quality System (CIWQS) number CW-208930, Waste Discharge Identification (WDID) number 7A360100011, and GeoTracker Global Identification number WDR100027897.

2. The WWTP is located outside the boundary of the Colorado River Basin Water Board (Regional Water Board) and is regulated by the California Regional Water Quality Control Board, Santa Ana Region (Santa Ana Water Board) under Waste Discharge Requirements (WDRs) Order R8-2005-0044.

3. The WWTP has the following types of treatment: preliminary treatment, secondary treatment, and sludge drying and treatment. Secondary treated wastewater from the WWTP is disposed of through three possible discharge points that are designated in Order R8-2005-0044 as Point 001, Point 002, and Point 003. The discharges from the WWTP at Points 002 and 003 are regulated by the Santa Ana Regional Water Quality Control Board. The majority of the treated wastewater is discharged through Discharge Point 001 into the Lucerne Valley to irrigate fodder, fiber, and seed crops. A minimal volume of treated wastewater is discharged through Points 002 and 003 for recycling and reuse at various sites for irrigation, dust control at construction sites, and wildlife habitat restoration in the Baldwin Lake.

4. This Order regulates the discharge from the WWTP at Point 001. Infrastructure associated with this discharge includes a concrete-lined reservoir and two overflow

ponds that are used to dispose of treated recycled wastewater by percolation and evaporation in the Lucerne Valley (Lucerne Valley Facility or Facility).

5. The Lucerne Valley Facility is located near the intersection of State Highway 247 (Old Woman Springs Road) and Camp Rock Road in the Lucerne Valley of San Bernardino County in Section 14, T4N, R1E, SBB&M, and Assessor's Parcel Number (APN) 0449-082-040000, 34.438554°N Latitude, -116.851225°W Longitude. The Facility's location is shown in **Attachment A**- Vicinity Map, made part of this Order by reference.

6. The Lucerne Valley Facility was most recently regulated by WDRs in Order R7-2016-0026, which was adopted by the Regional Water Board on June 30, 2016.

7. On October 28, 2020, the Discharger submitted an application and Report of Waste Discharge (ROWD) to the Regional Water Board, applying for updated WDRs for the Facility.

8. This Order updates the WDRs to comply with current laws and regulations applicable to the discharge. Accordingly, this Order supersedes WDRs in Order R7-2016-0026 upon the effective date of this Order, except for enforcement purposes.

Wastewater Treatment Facility and Discharge

9. Wastewater that is discharged at the Lucerne Valley Facility goes through preliminary and secondary treatment at the WWTP before it is sent via gravity to the concrete reservoir at the Lucerne Valley Facility. The WWTP components that are used for treatment are described below and the Process Flow Diagram for the WWTP is shown in **Attachment B**–Process Flow Diagram.

    a. **Preliminary Treatment**. Untreated wastewater flows to the preliminary treatment system, which consists of bar screens, aerated grit chamber with grit washer, and a flow bypass channel. This treatment stage removes screenings, rag material, and grit.

    b. **Secondary Treatment**. Effluent flows by gravity from the preliminary treatment system to three parallel oxidation ditches for secondary (biological) treatment and timed processes for nutrient (nitrogen) removal. The number of ditches in operation depends on the seasonal fluctuations of the influent flow. The effluent from the oxidation ditches flows into a system of three secondary clarifiers for removal of floatable and settleable solids/materials. The secondary treated effluent flows to two cement-lined balancing chambers and then flows to equalization storage ponds at the WWTP until pumped for offsite irrigation disposal.

    c. **Offsite Irrigation/Disposal**. Undisinfected secondary treated wastewater is pumped from the WWTP's main pump building (5.2 MGD) or auxiliary

pump building (9.2 MGD) approximately 16.5 miles to an offsite 2.26-million-gallon, concrete-lined reservoir (undisinfected secondary recycled water reservoir). This reservoir is located one mile south of the irrigation site. Wastewater from the reservoir flows by gravity through an outfall line connected to the irrigation system. In the event of an overflow at the concrete-lined reservoir, the wastewater flows by gravity to earthen overflow ponds located adjacent to the irrigation site.

10. Approximately 2.12 MGD of undisinfected secondary recycled water (as defined in California Code of Regulations, title 22, section 60301.900) is discharged to the Lucerne Valley Facility for irrigation of fodder and fiber crops. Undisinfected secondary wastewater was approved by the California Department of Public Health (succeeded by the State Water Resources Control Board's [State Water Board] Division of Drinking Water) for irrigation use at this site. Approximately 340 acres are currently irrigated at the Lucerne Valley Facility, with an additional 140 acres available for irrigation at the site. The effluent discharge limit of 4.8 MGD in this Order is based on the capacity of the irrigated crops to take up nitrogen. The Lucerne Valley Facility site layout is shown in **Attachment C**, made part of this Order by reference.

11. The State Water Board's Division of Drinking Water has established statewide reclamation criteria in California Code of Regulations, title 22, section 60301 et seq. for the use of recycled water and developed guidelines for specific uses. Section 60304(d)(4) allows the use of undisinfected, secondary recycled water for the surface irrigation of fodder and fiber crops and pasture for animals not producing milk for human consumption. BBARWA's Title 22 Engineering Report was initially approved on November 3, 1980 and was last updated November 4, 1998, to allow for the use of tertiary treated wastewater in the Big Bear Area.

12. The grazing of sheep on the irrigation site has been allowed under certain conditions, as outlined in a letter from Regional Water Board staff dated November 15, 1994, and in Discharge Specification D.18 of this Order.

13. No sewage sludge is discharged at the recycled water reuse site.

14. BBARWA's Self-Monitoring Reports (SMRs) from January 2016 through December 2020 characterize the WWTP effluent as follows:

Table 1. Effluent Characterization

Constituent	Units	Average	Maximum	Minimum
Flow	MGD	2.12	8.39	0.441

Constituent	Units	Average	Maximum	Minimum
20° C BOD_5[1]	mg/L[2]	8	36	ND[3]
TSS[4]	mg/L	8	44	1
pH	s.u.[5]	7.61	8.46	6.85
Total Dissolved Solids (TDS)	mg/L	441	520	350
Total Inorganic Nitrogen (TIN)[6]	mg/L	3.9	22.3	0.4
Total Nitrogen (TN)	mg/L	4.9	12	1.8
Nitrate as N	mg/L	1.7	7.7	0.04
Chloride	mg/L	56	87	34
Sulfate	mg/L	40	48	29
Fluoride	mg/L	0.43	0.61	0.24
Boron	mg/L	0.20	0.32	<0.1

Hydrogeologic Conditions

15. Lucerne Valley Groundwater Basin underlies Lucerne and North Lucerne Valleys and is bounded on the south by the San Bernardino Mountains and on the west by the Granite Mountains and the Helendale fault. The Ord Mountains bound the basin on the north. The Camp Rock fault and Kane Wash Area Groundwater Basin bound this basin on the east and the Fry Mountains bound this basin on the southeast. Parts of the eastern and southeastern boundaries are surface drainage

[1] 5-day biochemical oxygen demand at 20 degrees Celsius.

[2] Milligrams per Liter

[3] Not Detected at the laboratory's Reporting Limit.

[4] Total Suspended Solids

[5] Standard pH units

[6] Total Inorganic Nitrogen is the sum of nitrate, nitrite, and total ammonia.

divides. Surface water drains toward Lucerne (dry) Lake in the western portion of the basin, which has an altitude of 2,850 feet above sea level (Schaefer 1979[7]).

16. The principal water-bearing deposits are Quaternary age alluvium, and dune sand. The deposits are unconsolidated or semi-consolidated and the alluvium is composed of gravel, sand, silt, clay, and occasional boulders. Where saturated, the alluvium yields water freely to wells. The average specific yield for these deposits is 11 percent. Irrigation wells in the basin yield as much as 1,000 gallons per minute (Schaefer 1979).

17. BBARWA has three groundwater monitoring wells (MW-1-upgradient; MW-2-downgradient; and MW-3-downgradient). Groundwater levels in monitoring wells have increased since the wells were constructed in 1991. BBARWA has reported that the depth to groundwater at the Lucerne Valley Facility is within the range of 125 to 175 feet below ground surface (bgs) and groundwater flow direction is generally to the northwest, towards Lucerne Dry Lake.

18. Groundwater monitoring data collected from monitoring wells MW-1, MW-2, and MW-3 during the period from 2017 through 2020 show the following average characteristics:

Table 2. Groundwater Monitoring Data

Constituent	Units	MW-1	MW-2	MW-3
Depth to Groundwater	ft	170	125.2	138.1
TDS	mg/L	435.5	655.2	583
TN	mg/L	9.54	15.1	15.9
Nitrate as N	mg/L	8.97	14.5	15.4
Sulfate	mg/L	62.1	138.4	179.7
Chloride	mg/L	70.3	123.4	109.1
Fluoride	mg/L	0.19	0.14	0.24
Boron	mg/L	0.12	0.11	0.09
VOCs	ug/L	ND	ND	ND

[7] Schaefer, D.H. 1979. *Ground-Water Conditions and Potential for Artificial Recharge in Lucerne Valley, San Bernardino County, California*. U.S. Geological Survey Water Resources Investigations 78-118. 37 p.

19. Annual precipitation in the Lucerne Valley region averages about 14 inches.

20. Typically, November through April are considered wet weather, while May through October are considered dry weather months.

21. There are several domestic wells in the vicinity of the irrigation recycled use area and the evaporation/percolation ponds.

22. Water supply to the Big Bear area communities is from numerous groundwater production wells located in Big Bear Valley. TDS in the water supply averages about 280 mg/L based on data reported in the BBARWA's SMRs from 2017 through 2020.

23. BBARWA conducted a geotechnical study referenced as *Geotechnical Study, Irrigation Site, Lucerne Valley Area, San Bernardino County, California for Big Bear Area Regional Wastewater Agency, July 29, 1977,* as an initial investigation of the site for use for irrigation. The report shows that the site is underlain by soils consisting of fine to coarse, clean to silty sands containing various amounts of gravel from 5 to 24 feet below ground surface. Beneath this, to a depth of 60 to 100 feet below ground surface, the soil consists of fine to medium silty sands containing varying amounts of gravel and is locally cemented with calcium carbonate accumulated during deposition of the sediments. Bedrock underlies the older alluvium at a depth of 400 to 600 feet.

Basin Plan, Beneficial Uses, and Regulatory Considerations

24. The Water Quality Control Plan for the Colorado River Basin Region (Basin Plan), adopted on November 17, 1993 and most recently amended on January 8, 2019, designates beneficial uses, establishes water quality objectives, and contains implementation programs and policies to achieve those objectives for all waters addressed through the plan. Pursuant to Water Code section 13263, subdivision (a), WDRs must implement the Basin Plan and take into consideration the beneficial uses to be protected, the water quality objectives reasonably required for that purpose, other waste discharges, the need to prevent nuisance, and the provisions of Water Code section 13241.

25. The Facility is located within the Lucerne Hydrologic Unit, and the Basin Plan designates the following beneficial uses for groundwater:

    a. Municipal Supply (MUN),
    b. Industrial Supply (IND), and
    c. Agricultural Supply (AGR).

26. This Order establishes WDRs pursuant to division 7, chapter 4, article 4 of the Water Code for discharges that are not subject to regulation under Clean Water Act section 402 (33 U.S.C. § 1342).

27. These WDRs implement numeric and narrative water quality objectives for groundwater and surface waters established by the Basin Plan and other applicable state and federal laws and policies. The numeric objectives for groundwater designated for municipal and domestic supply include the maximum contaminant levels (MCLs) specified in California Code of Regulations, title 22, section 64421 et seq. Groundwater for use as domestic or municipal water supply (MUN) must not contain taste- or odor-producing substances in concentrations that adversely affect beneficial uses as a result of human activity.

28. It is the policy of the State of California that every human being has the right to safe, clean, affordable, and accessible water adequate for human consumption, cooking, and sanitary purposes. This Order promotes that policy by requiring discharges to meet MCLs designed to protect human health and ensure that water is safe for domestic use.

29. The discharge authorized by this Order, except for discharges of residual sludge and solid waste, are exempt from the solid waste requirements of California Code of Regulations, title 27, section 20005 et seq. This exemption is based on section 20090, subdivisions (a) and (b) of title 27 of the California Code of Regulations, which provides that discharges of domestic sewage or wastewater to land, including but not limited to evaporation ponds, percolation ponds, or subsurface leach fields are not subject to the requirements of title 27 if the following exemption conditions are met:

    a. The applicable regional water board has issued WDRs, reclamation requirements, or waived such issuance;

    b. The discharge is in compliance with the applicable water quality control plan; and

    c. The wastewater does not need to be managed according to chapter 11, division 4.5, title 22 of the California Code of Regulations as a “hazardous waste.”

30. The discharge of waste authorized by these WDRs satisfies the conditions to be exempted from the requirements of title 27 of the California Code of Regulations, because (1) the discharge is regulated by these WDRs; (2) these WDRs will ensure the discharge complies with the Basin Plan; and (3) the discharge will not be of a “hazardous waste.”

31. Consistent with Water Code section 13241, the Regional Water Board, in establishing the requirements contained herein, considered factors including, but not limited to, the following:

a. Past, present, and probable future beneficial uses of water;

b. Environmental characteristics of the hydrographic unit under consideration, including the quality of water available thereto;

c. Water quality conditions that could reasonably be achieved through the coordinated control of all factors which affect water quality in the area;

d. Economic considerations;

e. The need for developing housing within the region(s); and

f. The need to develop and use recycled water.

32. Water Code section 13267 authorizes the Regional Water Board to require technical and monitoring reports. The monitoring and reporting requirements in Monitoring and Reporting Program (MRP) R7-2021-0023 are necessary to demonstrate compliance with this Order. The State Water Resources Control Board's (State Water Board's) electronic database, GeoTracker Information Systems, facilitates the submittal and review of monitoring and reporting documents. The burden, including costs, of the MRP bears a reasonable relationship to the need for that information and the benefits to be obtained from that information.

33. Pursuant to Water Code section 13263, subdivision (g), the discharge of waste is a privilege, not a right, and adoption of this Order does not create a vested right to continue the discharge.

Antidegradation Analysis

34. State Water Board Resolution 68-16, entitled *Statement of Policy with Respect to Maintaining High Quality Waters in California* (Resolution 68-16), generally prohibits the Regional Water Board from authorizing discharges that will result in the degradation of high quality waters, unless it is demonstrated that any change in water quality will (a) be consistent with maximum benefit to the people of the state, (b) not unreasonably affect beneficial uses, and (c) not result in water quality less than that prescribed in state and regional policies (e.g., the violation of one or more water quality objectives). The discharger must also employ best practicable treatment or control (BPTC) to minimize the degradation of high quality waters. High quality waters are surface waters or areas of groundwater that have a baseline water quality better than required by water quality control plans and policies.

35. Some degradation of groundwater from the discharge to the irrigation recycled use area and the infiltration basins is consistent with Resolution 68-16, provided that the degradation:

a. Is confined to a reasonable area;

b. Is minimized by means of full implementation, regular maintenance, and optimal operation of BPTC measures by the Discharger;

c. Is limited to waste constituents typically encountered in domestic wastewater;

d. Does not unreasonably affect any beneficial uses of groundwater prescribed in the Basin Plan, and will not result in the violation of any water quality objective; and

e. Is consistent with the maximum benefit to the people of the state.

36. Recycled water used for irrigation at the Lucerne Valley Facility is treated to secondary standards and has undergone substantial removal of soluble organic matter, solids, and nitrogen treatment. Constituents in the wastewater effluent that have the potential to degrade groundwater include nitrogen, chloride, sulfate, TDS, and total coliform. Each of these constituents is discussed below:

a. **Nitrogen.** The Primary Maximum Contaminant Level (MCL) found in California Code of Regulations, title 22, section 64431 for nitrate plus nitrite as nitrogen is 10 mg/L. To account for the fate of transport for the various components of total nitrogen, as a conservative value, it is assumed that all nitrogen present converts to nitrate/nitrite. BBARWA's SMRs report an average of 3.9 mg/L for Total Inorganic Nitrogen and 4.9 mg/L for Total Nitrogen between January 2016 and December 2020. BBARWA conducted a study of the groundwater in the vicinity of the recycled water irrigation use site in September 2016 which included an analysis of potential sources of nitrate in the groundwater other than BBARWA recycled water. Some of the sources included onsite farming practices, irrigation and fertilization in excess of plant demands, and potential upgradient sources, such as discharges from individual onsite septic systems. The study found that nitrate concentrations have been increasing in the upgradient groundwater monitoring well but have been decreasing in the downgradient monitoring wells. To verify no degradation due to nitrogen is occurring, this Order requires quarterly total nitrogen and nitrate as nitrogen monitoring in the groundwater monitoring wells. This Order also provides an average monthly effluent limit for total nitrogen of 10 mg/L.

b. **Chloride and Sulfate**. The "recommended" Secondary MCLs in California Code of Regulations, title 22, section 64449 for chloride and sulfate are both 250 mg/L. Concentrations of chloride and sulfate are included in TDS measurements. BBARWA's SMRs report an average of 56 and 40 mg/L for chloride and sulfate, respectively, between January 2016 and December 2020. Additionally, BBARWA's SMRs, for the same time period, report a maximum of 87 and 48 mg/L for chloride and sulfate, respectively.

BBARWA occasionally experience increases in chloride due to the use of salt and brine on local roadways prior to snowstorm events. To evaluate the incremental degradation due to chloride and sulfate, this Order requires quarterly chloride and sulfate monitoring in the groundwater monitoring wells. This Order also provides an average monthly effluent limit of 60 mg/L and a daily maximum effluent limit of 80 mg/L for both chloride and sulfate.

c. **TDS.** The Secondary MCL specified in California Code of Regulations, title 22, section 64449 for TDS ranges between the "recommended" consumer acceptance level of 500 mg/L and the "upper" consumer acceptance level of 1,000 mg/L, if it is neither reasonable nor feasible to provide more suitable waters. The typical incremental addition of dissolved salts from domestic water usage in wastewater treatment plants ranges from 150 to 380 mg/L. Domestic water supply to the Big Bear area communities showed an average concentration of about 280 mg/L based on data reported in the BBARWA's SMRs from 2017 through 2020. From 2016 to December 2020, treated wastewater discharged had an average TDS concentration of approximately 440 mg/L. Thus, the average TDS increase over the domestic water supply in the discharge was about 160 mg/L. Based on the study that the Discharger conducted in September 2016, which analyzed the impacts of groundwater by the discharge, the results would help establish an appropriate effluent limitation for TDS. The study states that the average TDS concentration in the Lucerne Valley Groundwater Basin is closer to 500 mg/L in the vicinity of the discharge location, whereas the Basin as a whole has an average of approximately 1,100 mg/L. Downgradient TDS concentrations in groundwater were found to be equal to or above concentrations of water delivered to the discharge location and the basin-wide average TDS concentration is above that of the delivered water. Therefore, the delivered water is not expected to degrade the existing groundwater quality or limit existing downgradient beneficial uses. To verify there is no degradation due to TDS is occurring, this Order includes quarterly TDS monitoring in the groundwater monitoring wells. This Order also provides an effluent limit for TDS of 550 mg/L over a 12-month period.

d. **Total Coliform.** Secondary treatment reduces fecal coliform densities by 90 to 99%; the remaining organisms in effluent are still 10^5 to 10^6 most probable number (MPN)/100 mL (U.S. Environmental Protection Agency, *Design Manual: Municipal Wastewater Disinfection*, EPA/625/1-86/021, October 1986.) Other sources of *E. Coli* may include residential septic systems and runoff from animal waste, which are both present in the areas surrounding the groundwater monitoring wells. Given the depth to groundwater, which is approximately 125 to 175 feet, it is not likely that pathogen-indicator bacteria will reach groundwater in excess of that prescribed in California Code of Regulations, title 22, section 64426.1, due to significant attenuation and removal in the soils in the vadose zone. To evaluate the potential degradation to groundwater due to pathogens, this

Order includes quarterly *E. coli* monitoring in the groundwater monitoring wells and monthly *E. coli* monitoring in the effluent.

37. The discharge of wastewater from the Facility, as permitted herein, reflects BPTC. The Facility incorporates:

    a. Technology for secondary treated domestic wastewater;

    b. Structural controls to dispose of waste constituents in a designated area;

    c. A network of groundwater monitoring wells;

    d. An operation and maintenance manual;

    e. An Irrigation Management Plan;

    f. Staffing to ensure proper operation and maintenance; and

    g. A standby emergency power generator of sufficient size to operate the treatment plant and ancillary equipment during periods of loss of commercial power.

38. Degradation of groundwater by some of the typical waste constituents associated with discharges from a facility treating domestic wastewater, after effective source control, treatment, and control measures are implemented, is consistent with the maximum benefit to the people of the state. The technology, energy, water recycling, and waste management advantages of regional utility service far exceed any benefits derived from reliance on numerous, concentrated individual wastewater systems, and the impact on water quality will be substantially less. These factors, when taken in conjunction with the associated increase in waste constituents, are consistent with the maximum benefit to the people of the state. Accordingly, the discharge, as authorized, is consistent with the antidegradation provisions of Resolution 68-16 and applicable water quality objectives.

Stormwater

39. Federal regulations for stormwater discharges were promulgated by the U.S. Environmental Protection Agency on November 16, 1990 (40 C.F.R. parts 122, 123, and 124) to implement the Clean Water Act's stormwater program set forth in Clean Water Act section 402, subdivision (p) (33 U.S.C. § 1342(p)). In relevant part, the regulations require specific categories of facilities that discharge stormwater associated with industrial activity to "waters of the United States" to obtain National Pollutant Discharge Elimination System (NPDES) permits and to require control of such pollutant discharges using Best Available Technology Economically Achievable (BAT) and Best Conventional Pollutant Control Technology (BCT) to prevent and reduce pollutants and any more stringent controls necessary to meet water quality standards.

40. The State Water Board adopted Order 2014-0057-DWQ (NPDES No. CAS000001), *General Permit for Storm Water Discharges Associated with Industrial Activities* (Industrial General Permit) on July 1, 2015. Facilities used in the storage, treatment, recycling, and reclamation of municipal or domestic sewage with a design flow of one million gallons per day or more, or that are required to have an approved pretreatment program under 40 Code of Federal Regulations part 403, are required to enroll under the Industrial General Permit, unless there is no discharge of industrial stormwater to waters of the United States.

CEQA and Public Participation

41. Pursuant to California Code of Regulations, title 14, section 15301, the issuance of these WDRs, which govern the operation of an existing facility involving negligible or no expansion of use beyond that previously existing, is exempt from the provisions of the California Environmental Quality Act (CEQA), Public Resources Code section 21000 et seq.

42. The Regional Water Board has notified the Discharger and all known interested agencies and persons of its intent to issue WDRs for this discharge, and has provided them with an opportunity for a public meeting and to submit comments.

43. The Regional Water Board, in a public meeting, heard and considered all comments pertaining to this discharge.

IT IS HEREBY ORDERED that Order R7-2016-0026 is rescinded upon the effective date of this Order, except for enforcement purposes, and, in order to meet the provisions contained in division 7 of the Water Code, and regulations adopted thereunder, the Discharger shall comply with the following:

A. Effluent Limitations

1. Effluent used for irrigation in the recycled use area or discharged into the overflow evaporation/percolation ponds for disposal shall not exceed the following effluent limits:

Table 3. Effluent Limitations

Constituent	Units	Monthly Average	Weekly Average	Daily Maximum
20°C BOD_5	mg/L	30	45	--
Total Suspended Solids	mg/L	30	45	--
Chloride	mg/L	60	--	80

Constituent	Units	Monthly Average	Weekly Average	Daily Maximum
Sulfate	mg/L	60	--	80
Boron	mg/L	--	--	0.75
Total Nitrogen	mg/L	10	--	--

2. The 30-day average daily dry weather discharge for irrigation shall not exceed 4.8 MGD.

3. The hydrogen ion concentration (pH) in the effluent discharge for irrigation shall be maintained within the limits of 6.0 to 9.0 standard units.

4. The TDS concentration of the effluent shall not exceed a 12-month average effluent limit of 550 mg/L. The reported concentration shall be determined by the arithmetic mean of the last twelve months of monitoring.

5. The overflow evaporation/percolation ponds shall be maintained so that they continuously operate in aerobic conditions. The dissolved oxygen content in the upper zone (one foot) of the infiltration basins shall be equal to or greater than 1.0 mg/L.

B. Receiving Water Limitations

1. The discharge of wastewater from the Facility shall not cause groundwater to: exceed applicable water quality objectives; acquire taste, odor, toxicity, or color that create nuisance conditions; impair beneficial uses; or contain constituents in excess of California Maximum Contaminant Levels (MCLs), as set forth in title 22 of the California Code of Regulations (including, but not limited to, section 64426.1 for bacteriological constituents; section 64431 for inorganic chemicals; section 64444 for organic chemicals; and section 64678 for lead and copper).

C. Discharge Prohibitions

1. Discharge of waste classified as “hazardous,” as defined in California Code of Regulations, title 27, section 20164, or “designated,” as defined in Water Code section 13173 and California Code of Regulations, title 27, section 20164, is prohibited.

2. The discharge of treated wastewater at a location other than the designated disposal areas or as recycled water used for irrigation at approved use areas, is prohibited.

3. The discharge of wastewater and/or recycled water to surface waters or surface drainage courses is prohibited.

4. The Discharger shall not accept waste in excess of the design treatment capacity of the Facility's disposal system.

5. Surfacing or ponding of wastewater outside of the designated disposal locations is prohibited.

6. Application of treated wastewater for irrigation in excess of agronomic rates is prohibited.

7. Bypass or overflow of untreated or partially-treated waste is prohibited, except as permitted in Standard Provision E.13.

8. The discharge of wastewater to a location or in a manner different from that described in this Order is prohibited.

9. The discharge of wastewater to land not owned or controlled by the Discharger, or not authorized for such use, is prohibited.

10. The storage, treatment, or disposal of wastes from the Facility shall not cause contamination, pollution, or nuisance as defined in Water Code section 13050, subdivisions (k), (l), and (m).

D. Discharge Specifications

1. The Discharger shall maintain sufficient freeboard in the overflow evaporation/percolation ponds to accommodate seasonal precipitation and to contain a 100-year storm event, but in no case no less than two (2) feet of freeboard (measured vertically). Freeboard shall be utilized for wake and waves of fluid motion and emergency or natural disaster purposes only.

2. All treatment, storage, and disposal areas shall be designed, constructed, operated and maintained to prevent inundation or washout due to floods with a 100-year return frequency.

3. Evaporation/percolation ponds shall have sufficient capacity to accommodate allowable wastewater flow, design seasonal precipitation, ancillary inflow, and infiltration. Design seasonal precipitation shall be based on total annual precipitation using a return period of 100 years, distributed monthly in accordance with historical rainfall patterns.

4. The evaporation/percolation ponds shall be managed to prevent breeding of mosquitoes. In particular:

a. An erosion control program should ensure that small coves and irregularities are not created around the perimeter of the water surface.

b. Weeds shall be minimized through control of water depth, harvesting, or herbicides.

c. Dead algae, vegetation, and debris shall not accumulate on the water surface.

5. Public contact with wastewater shall be precluded through such means as fences, signs, or other acceptable alternatives.

6. Objectionable odors originating at the Facility shall not be perceivable beyond the property boundary.

7. The evaporation/percolation ponds shall be maintained and operated so as to maximize infiltration and minimize the increase of salinity in the groundwater.

8. Onsite wastes, including windblown spray from recycled water application, shall be strictly confined to the lands specifically designated for the disposal operation, and onsite irrigation practices shall be managed so there is no runoff of effluent from irrigated areas.

9. No irrigation with, or impoundment of, undisinfected secondary recycled water shall take place within 150 feet of any domestic water supply well.

10. No spray irrigation of any recycled water shall take place within 100 feet of a residence or a place where public exposure could be similar to that of a park, playground or schoolyard.

11. Except as allowed under California Code of Regulations, title 17, section 7604, no physical connection shall be made or allowed to exist between any recycled water system and any separate system conveying potable water.

12. Undisinfected secondary recycled water, as defined in California Code of Regulations, title 22, section 60301.900, may only be used for irrigation in the following applications:

a. Orchards where the recycled water does not come into contact with the edible portion of the crop;

b. Vineyards where the recycled water does not come into contact with the edible portion of the crop;

c. Non-food bearing trees (Christmas tree farms are included in this category provided no irrigation with recycled water occurs for a period of 14 days prior to harvesting or allowing access by the general public);

d. Fodder and fiber crops and pasture for animal not producing milk for human consumption;

e. Seed crops not eaten by humans;

f. Food crops that must undergo commercial pathogen-destroying processing before being consumed by humans; and

g. Ornamental nursery stock and sod farms provided no irrigation with recycled water occurs for a period of 14 days prior to harvesting, retail sale, or allowing access by the general public.

13. No recycled water used for irrigation, or soil that has been irrigated with recycled water, shall come into contact with edible portions of food crops eaten raw by humans.

14. The delivery or use of recycled water shall conform with the reclamation criteria contained in California Code of Regulations, title 22 or amendments thereto, for the irrigation of food crops, irrigation of fodder, fiber, and seed crops, landscape irrigation, supply of recreational impoundments, and groundwater recharge.

15. Prior to delivering recycled water to any new user, the Discharger shall submit to the Regional Water Board a report discussing any new distribution system being constructed by the Discharger to provide service to the new user.

16. Recycled water shall not be delivered to any new user who has not first received a discharge permit from the Regional Water Board and approval from the State Water Board’s Division of Drinking Water.

17. Treated or untreated sludge or similar solid waste materials shall be disposed of at locations approved by the Regional Water Board’s Executive Officer.

18. Grazing of sheep on the irrigation site is allowed only under the following conditions, unless otherwise approved by the Regional Water Board 's Executive Officer:

a. Grazing will only be conducted in October or November after the last cutting of hay has been baled;

b. Grazing animals will not be allowed into a portion of the site until 10 days after it was last irrigated;

c. Temporary fences will be erected to contain the grazing animals in an area of 40 acres or less;

d. Only ewes that are about to lamb or ewes with newly born will be grazed;

e. No animals will be sold for slaughter within 90 days after grazing; and

f. No milk produced by sheep that have grazed at the irrigation site shall be used for human consumption.

E. Standard Provisions

1. **Noncompliance.** The Discharger shall comply with all of the terms, requirements, and conditions of this Order and MRP R7-2021-0023. Noncompliance is a violation of the Porter-Cologne Water Quality Control Act (Water Code, § 13000 et seq.) and grounds for: (1) an enforcement action; (2) termination, revocation and reissuance, or modification of these waste discharge requirements; or (3) denial of an Order renewal application.

2. **Enforcement.** The Regional Water Board reserves the right to take any enforcement action authorized by law. Accordingly, failure to timely comply with any provisions of this Order may subject the Discharger to enforcement action. Such actions include, but are not limited to, the assessment of administrative civil liability pursuant to Water Code sections 13323, 13268, and 13350, a Time Schedule Order (TSO) issued pursuant to Water Code section 13308, or referral to the California Attorney General for recovery of judicial civil liability.

3. **Proper Operation and Maintenance.** The Discharger shall at all times properly operate and maintain all systems and components of collection, treatment, and control installed or used by the Discharger to achieve compliance with this Order. Proper operation and maintenance includes, but is not limited to, effective performance, adequate process controls, and appropriate quality assurance procedures. This provision requires the operation of backup or auxiliary facilities/systems when necessary to achieve compliance with this Order. All systems in service or reserved shall be inspected and maintained on a regular basis. Records of inspections and maintenance shall be retained and made available to the Regional Water Board on request.

4. **Reporting of Noncompliance.** The Discharger shall report any noncompliance that may endanger human health or the environment,

including spills in excess of one thousand (1,000) gallons occurring within the Facility or collection system. Information shall be provided orally to the Regional Water Board office and the Office of Emergency Services within twenty-four (24) hours of when the Discharger becomes aware of the incident. If noncompliance occurs outside of business hours, the Discharger shall leave a message on the Regional Water Board's office voicemail. A written report shall also be provided within five business days of the time the Discharger becomes aware of the incident. The written report shall contain a description of the noncompliance and its cause, the period of noncompliance, the anticipated time to achieve full compliance, and the steps taken or planned to reduce, eliminate, and prevent recurrence of the noncompliance. A final certified report must be submitted through the online GeoTracker system, within 15 calendar days of the conclusion of spill response and remediation. Additional information may be added to the certified report, in the form of an attachment, at any time. All other forms of noncompliance shall be reported with the Discharger's next scheduled Self-Monitoring Report (SMR), or earlier if requested by the Regional Water Board's Executive Officer or if required by an applicable standard for sludge use and disposal.

5. **Duty to Mitigate.** The Discharger shall take all reasonable steps to minimize or prevent any discharge in violation of this Order that has a reasonable likelihood of adversely affecting human health or the environment.

6. **Material Changes.** Prior to any modifications which would result in any material change in the quality or quantity of wastewater treated or discharged, or any material change in the location of discharge, the Discharger shall report all pertinent information in writing to the Regional Water Board, and if required by the Regional Water Board, obtain revised requirements before any modifications are implemented.

7. **Design Capacity Report.** The Discharger shall provide a report to the Regional Water Board when it determines that the Facility's average dry-weather flow rate for any month exceeds 80 percent of the design capacity. The report should indicate what steps, if any, the Discharger intends to take to provide for the expected wastewater treatment capacity necessary when the plant reaches design capacity.

8. **Operational Personnel.** The Facility shall be supervised and operated by persons possessing certification of appropriate grade pursuant to section 3680, chapter 26, division 3, title 23 of the California Code of Regulations.

9. **Familiarity with Order.** The Discharger shall ensure that all site-operating personnel are familiar with the content of this Order and maintain a copy of this Order at the site.

10. **Inspection and Entry.** The Discharger shall allow the Regional Water Board, or an authorized representative, upon presentation of credentials and other documents as may be required by law, to:

    a. Enter the premises regulated by this Order, or the place where records are kept under the conditions of this Order;

    b. Have access to and copy, at reasonable times, records kept under the conditions of this Order;

    c. Inspect at reasonable times any facilities, equipment (including monitoring and control equipment), practices, or operations regulated or required under this Order; and

    d. Sample or monitor at reasonable times, for the purpose of assuring compliance with this Order or as otherwise authorized by the Water Code, any substances or parameters at this location.

11. **Records Retention.** The Discharger shall retain copies of all reports required by this Order and the associated MRP. Records shall be maintained for a minimum of five years from the date of the sample, measurement, report, or application. Records may be maintained electronically. This period may be extended during the course of any unresolved litigation regarding this discharge or when requested by the Regional Water Board's Executive Officer.

12. **Change in Ownership.** This Order is not transferable to any person without written approval by the Regional Water Board's Executive Officer. Prior to any change in ownership of this operation, the Discharger shall notify the Regional Water Board's Executive Officer in writing at least 30 days in advance. The notice must include a written transfer agreement between the existing owner and the new owner. At a minimum, the transfer agreement must contain a specific date for transfer of responsibility for compliance with this Order and an acknowledgment that the new owner or operator is liable for compliance with this Order from the date of transfer. The Regional Water Board may require modification or revocation and reissuance of this Order to change the name of the Discharger and incorporate other requirements as may be necessary under the Water Code.

13. **Bypass.** Bypass (i.e., the intentional diversion of waste streams from any portion of the treatment facilities, except diversions designed to meet variable effluent limits) is prohibited. The Regional Water Board may take enforcement action against the Discharger for bypass unless:

    a. Bypass was unavoidable to prevent loss of life, personal injury, or severe property damage. Severe property damage means substantial physical damage to property, damage to the treatment

facilities that causes them to be inoperable, or substantial and permanent loss of natural resources reasonably expected to occur in the absence of a bypass. Severe property damage does not mean economic loss caused by delays in fee collection; and

b. There were no feasible alternatives to bypass, such as the use of auxiliary treatment facilities or retention of untreated waste. This condition is not satisfied if adequate back-up equipment was not installed to prevent bypass occurring during equipment downtime, or preventative maintenance; or

c. Bypass is (1) required for essential maintenance to ensure efficient operation; (2) neither effluent nor receiving water limitations are exceeded and (3) the Discharger notifies the Regional Water Board ten (10) days in advance.

In the event of an unanticipated bypass, the Discharger shall immediately report the incident to the Regional Water Board. During non-business hours, the Discharger shall leave a message on the Regional Water Board's office voicemail. A written report shall be provided within five (5) business days after the Discharger is aware of the incident. The written report shall include a description of the bypass, any noncompliance, the cause, period of noncompliance, anticipated time to achieve full compliance, and steps taken or planned to reduce, eliminate, and prevent recurrence of the noncompliance.

14. **Backup Generators.** Standby, power generating facilities shall be available to operate the Facility during a commercial power failure.

15. **Format of Technical Reports.** The Discharger shall furnish, under penalty of perjury, technical monitoring program reports, and such reports shall be submitted in accordance with California Code of Regulations, title 23, division 3, chapter 30, as raw data uploads electronically over the Internet into the State Water Board's GeoTracker database. Documents that are normally mailed by the Discharger to the Regional Water Board, such as regulatory documents, narrative monitoring reports or materials, and correspondence, shall also be uploaded into GeoTracker in the appropriate Microsoft Office software application format, such as Word or Excel files, or as a Portable Document Format (PDF) file. Large documents must be split into appropriately-labelled, manageable file sizes and uploaded into GeoTracker.

16. **Qualified Professionals.** In accordance with Business and Professions Code sections 6735, 7835, and 7835.1, engineering and geologic evaluations and judgments shall be performed by or under the direction of California registered professionals (i.e., civil engineer, engineering geologist, geologist, etc.) competent and proficient in the fields pertinent to

the required activities. All technical reports required under this Order that contain work plans, describe the conduct of investigations and studies, or contain technical conclusions and recommendations concerning engineering and geology shall be prepared by or under the direction of appropriately-qualified professional(s), even if not explicitly stated. Each technical report submitted by the Discharger shall contain a statement of qualifications of the responsible licensed professional(s) as well as the professional's signature and/or stamp of the seal. Additionally, all field activities are to be conducted under the direct supervision of one or more of these professionals.

17. **Certification Under Penalty of Perjury.** All technical reports required in conjunction with this Order shall include a statement by the Discharger, or an authorized representative of the Discharger, certifying under penalty of perjury under the laws of the State of California, that the reports were prepared under his or her supervision in accordance with a system designed to ensure that qualified personnel properly gathered and evaluated the information submitted, and that based on his or her inquiry of the person or persons who manage the system, the information submitted is, to the best of his or her knowledge and belief, true, complete, and accurate.

18. **Violation of Law.** This Order does not authorize violation of any federal, state, or local laws or regulations.

19. **Property Rights.** This Order does not convey property rights of any sort, or exclusive privileges, nor does it authorize injury to private property or invasion of personal rights.

20. **Modification, Revocation, Termination.** This Order may be modified, revoked and reissued, or terminated for cause. The filing of a request by the Discharger for an Order modification, rescission, or reissuance, or the Discharger’s notification of planned changes or anticipated noncompliance, does not stay any Order condition. Causes for modification include, but are not limited to, the violation of any term or condition contained in this Order, a material change in the character, location, or volume of discharge, a change in land application plans or sludge use/disposal practices, or the adoption of new regulations by the State Water Board, Regional Water Board (including revisions to the Basin Plan), or federal government.

21. **Severability.** The provisions of this Order are severable. If any provision of this Order is found invalid, the remainder of these requirements shall not be affected.

Any person aggrieved by this Regional Water Board action may petition the State Water Board for review in accordance with Water Code section 13320 and California Code of Regulations, title 23, section 2050 et seq. The State Water

Board must receive the petition by 5:00 p.m. on the 30th day after the date of this Order; if the 30th day falls on a Saturday, Sunday, or state holiday, the petition must be received by the State Water Board by 5:00 p.m. on the next business day. Copies of the statutes and regulations applicable to filing petitions are available on the State Water Board's website and can be provided upon request.

MONITORING AND REPORTING PROGRAM R7-2021-0023
FOR
BIG BEAR AREA REGIONAL WASTEWATER AGENCY, OWNER/OPERATOR
EXPORT OF RECYCLED WATER TO LUCERNE VALLEY
LUCERNE VALLEY-SAN BERNARDINO COUNTY

This Monitoring and Reporting Program (MRP) is issued pursuant to Water Code section 13267 and describes requirements for monitoring the relevant wastewater system and groundwater quality. The Discharger shall not implement any changes to this MRP unless and until a revised MRP is issued by the Regional Water Board or its Executive Officer.

The Discharger owns and operates the wastewater treatment system that is subject to Order R7-2021-0023. The reports required herein are necessary to ensure that the Discharger complies with the Order. Pursuant to Water Code section 13267, the Discharger shall implement the MRP and shall submit monitoring reports described herein.

A. Sampling and Analysis General Requirements

1. **Testing and Analytical Methods.** The collection, preservation, and holding times of all samples shall be in accordance with U.S. Environmental Protection Agency (USEPA)-approved procedures. All analyses shall be conducted in accordance with the latest edition of either the USEPA's *Guidelines Establishing Test Procedures for Analysis of Pollutants Under the Clean Water Act* (40 C.F.R. part 136) or *Test Methods for Evaluating Solid Waste: Physical/Chemical Methods Compendium* (SW-846), unless otherwise specified in the MRP or approved by the Regional Water Board's Executive Officer.

2. **Laboratory Certification.** All analyses shall be conducted by a laboratory certified by the State Water Board, Division of Drinking Water's Environmental Laboratory Accreditation Program (ELAP), unless otherwise approved by the Regional Water Board's Executive Officer.

3. **Reporting Levels.** All analytical data shall be reported with method detection limits (MDLs) and with either the reporting level or limits of quantitation (LOQs) according to 40 Code of Federal Regulations part 136, Appendix B. The laboratory reporting limit for all reported monitoring data shall be no greater than the practical quantitation limit (PQL).

4. **Sampling Location(s).** Samples shall be collected at the location(s) specified in the WDRs. If no location is specified, sampling shall be conducted at the most representative sampling point available.

5. **Representative Sampling.** All samples shall be representative of the volume and nature of the discharge or matrix of material sampled. The time, date, and location of each grab sample shall be recorded on the chain of custody form for the sample. If composite samples are collected, the basis for sampling (time or flow weighted) shall be approved by Regional Water Board staff.

6. **Instrumentation and Calibration.** All monitoring instruments and devices used by the Discharger shall be properly maintained and calibrated to ensure their continued accuracy. Any flow measurement devices shall be calibrated at least once per year to ensure continued accuracy of the devices. In the event that continuous monitoring equipment is out of service for a period greater than 24 hours, the Discharger shall obtain representative grab samples each day the equipment is out of service. The Discharger shall correct the cause(s) of failure of the continuous monitoring equipment as soon as practicable. The Discharger shall report the period(s) during which the equipment was out of service and if the problem has not been corrected, shall identify the steps which the Discharger is taking or proposes to take to bring the equipment back into service and the schedule for these actions.

7. **Field Test Instruments.** Field test instruments (such as those used to test pH, dissolved oxygen, and electrical conductivity) may be used provided that:

    a. The user is trained in proper use and maintenance of the instruments;

    b. The instruments are field calibrated prior to monitoring events at the frequency recommended by the manufacturer;

    c. Instruments are serviced and/or calibrated by the manufacturer at the recommended frequency; and

    d. Field calibration reports are submitted.

8. **Records Retention.** The Discharger shall retain records of all monitoring information, including all calibration and maintenance records and all original strip chart recordings for continuous monitoring instrumentation, for a minimum of five (5) years from the date of the sampling or measurement. This period may be extended by request of the Regional Water Board's Executive Officer at any time. Records of monitoring information shall include:

a. The date, exact place, and time of sampling or measurement(s);

b. The individual(s) who performed the sampling or measurement(s);

c. The date(s) analyses were performed;

d. The individual(s) who performed the analyses;

e. The analytical techniques or method used; and

f. All sampling and analytical results, including:

i. units of measurement used;

ii. minimum reporting limit for the analyses;

iii. results less than the reporting limit but above the method detection limit (MDL);

iv. data qualifiers and a description of the qualifiers;

v. quality control test results (and a written copy of the laboratory quality assurance plan);

vi. dilution factors, if used; and

vii. sample matrix type.

9. **Inoperative Facility.** If the Facility is not in operation, or there is no discharge during a required reporting period, the Discharger shall forward a letter to the Regional Water Board indicating that there has been no activity during the required reporting period.

B. Effluent Monitoring

1. Representative samples of the undisinfected secondary recycled water shall be taken at the WWTP. The samples shall be analyzed for the following constituents and according to the following schedule:

Constituent	Units	Type of Sample	Monitoring Frequency	Reporting Frequency
Irrigation Flow	MGD	Flow Meter Reading	Daily	Monthly

Constituent	Units	Type of Sample	Monitoring Frequency	Reporting Frequency
20°C BOD_5[8]	mg/L	24 Hr. Composite	2x/Month	Monthly
Total Suspended Solids (TSS)	mg/L	24 Hr. Composite	2x/Month	Monthly
pH	s.u.[9]	Grab	Daily	Monthly
Dissolved Oxygen[10]	mg/L	Grab	Monthly	Monthly
Total Dissolved Solids (TDS)	mg/L	24 Hr. Composite	Monthly	Monthly
Sulfate	mg/L	24 Hr. Composite	Monthly	Monthly
Chloride	mg/L	24 Hr. Composite	2x/Month	Monthly
Fluoride	mg/L	24 Hr. Composite	Monthly	Monthly
Nitrate as N	mg/L	24 Hr. Composite	Monthly	Monthly
Total Nitrogen	mg/L	24 Hr. Composite	Monthly	Monthly
E. Coli	MPN/100mL[11]	Grab	Monthly	Monthly
Volatile Organic Compounds (VOCs)	µg/L[12]	24 Hr. Composite	Annually	Annually

[8] 5-Day Biochemical Oxygen Demand at 20 degrees Celsius.

[9] Standard pH units

[10] Dissolved Oxygen shall be monitored at the upper one-foot layer of the storage or percolation ponds.

[11] Most Probable Number per 100 milliliters.

[12] Micrograms per liter

C. Overflow Pond Monitoring

1. During months when the overflow evaporation/percolation ponds are not used, the Discharger shall report that there has been no activity. During months when the overflow evaporation/percolation ponds are in use, the ponds shall be monitored according to the following schedule:

Constituent	Units	Type of Sample	Monitoring Frequency	Reporting Frequency
Flow	MGD	Flow Measurement	Daily	Monthly
Dissolved Oxygen	mg/L	Grab	2x/Month	Monthly
pH	s.u.	Grab	2x/Month	Monthly
Total Dissolved Solids	mg/L	Grab	2x/Month	Monthly
Freeboard	ft	Measurement	2x/Month	Monthly

D. Domestic Water Supply Monitoring

1. The domestic water supply shall be a flow weighted composite sample monitored at the water supply production wells in Big Bear Valley and include notations of which wells are non-operating for a reporting period and monitored according to the following schedule:

Constituent	Units	Type of Sample	Monitoring Frequency	Reporting Frequency
Total Dissolved Solids	mg/L	Grab	Quarterly	Quarterly
General Minerals[13]	mg/L	Grab	Annually	Annually

[13] General Minerals shall include: total dissolved solids, calcium, chloride, fluoride, iron, magnesium, manganese, nitrate, potassium, sodium, sulfate, barium, total alkalinity (including alkalinity series), and hardness.

E. Groundwater Monitoring

1. The groundwater monitoring wells shall be monitored according to the following schedule:

Constituent	Units	Type of Sample	Monitoring Frequency	Reporting Frequency
Depth to Groundwater	ft (msl)[14]	Measurement	Quarterly	Quarterly
Groundwater Gradient[15]	NA	Direction	Quarterly	Quarterly
Total Nitrogen	mg/L	Grab	Quarterly	Quarterly
Nitrate as N	mg/L	Grab	Quarterly	Quarterly
Chloride	mg/L	Grab	Quarterly	Quarterly
Fluoride	mg/L	Grab	Quarterly	Quarterly
Sulfate	mg/L	Grab	Quarterly	Quarterly
E. Coli	MPN/100mL	Grab	Quarterly[16]	Quarterly
Total Dissolved Solids	mg/L	Grab	Quarterly	Quarterly
Boron	mg/L	Grab	Quarterly	Quarterly
VOCs	μg/L	Grab	Annually	Annually

F. Reporting Requirements

1. Daily, weekly, and monthly monitoring shall be included in the Monthly Self-Monitoring Reports (SMRs). Monthly SMRs shall be submitted by the **15th day of the following month.** Quarterly SMRs shall be submitted by

[14] Above mean sea level.

[15] Groundwater flow direction.

[16] After two years of groundwater monitoring that show consistent negligible impacts to groundwater, the Discharger may request to have the monitoring schedule revised with Executive Officer approval.

January 15th, April 15th, July 15th, and October 15th. Annual SMRs shall be submitted by **January 31st** of the following year.

2. SMRs shall include, at a minimum, the following:

   a. **Cover Letter.** A transmittal letter summarizing the essential points in the report.

   b. **Maps.** Maps depicting the Facility layout and the location of sampling points.

   c. **Summary of Monitoring Data.** Tables of the data collected. The tables shall include all of the data collected to-date at each monitoring point, organized in chronological order, with the oldest data in the top row and progressively newer data in rows below the top row. Each row shall be a monitoring event and each column shall be a separate parameter at a single location (or a single average, as appropriate).

   d. **Graphical Display.** Graphs depicting monitoring parameters through time, with the concentrations being the y-axis and time being the x-axis. Logarithmic scales can be used for values that vary by orders of magnitude. Individual graphs can combine multiple locations or multiple chemicals if that allows the data to be compared more easily.

   e. **Compliance Summary.** Identification of any violations found since the last report was submitted, and actions taken or planned for correcting each violation. If the Discharger previously submitted a report describing corrective actions and/or a time schedule for implementing the corrective actions, reference to the previous correspondence will be satisfactory. If no violations have occurred since the last submittal, this shall be stated.

3. SMRs shall be certified under penalty of perjury to be true and correct. Each SMR submitted to the Regional Water Board shall contain the following completed declaration:

   “I declare under the penalty of law that I have personally examined and am familiar with the information submitted in this document, and that based on my inquiry of those individuals immediately responsible for obtaining the information, I believe that the information is true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fine and imprisonment for knowing violations.

   Executed on the _____day of _____ at _____

_____(Signature)

_____(Title)"

4. The SMRs and any other information requested by the Regional Water Board shall be signed by a principal executive officer or ranking elected official. A duly authorized representative of the Discharger may sign the documents if:

    a. The authorization is made in writing by the person described above;

    b. The authorization specified an individual or person having responsibility for the overall operation of the regulated disposal system; and

    c. The written authorization is submitted to the Regional Water Board's Executive Officer.

5. The results of any analysis taken more frequently than required at the locations specified in this MRP shall be reported to the Regional Water Board.

6. As specified in Standard Provision F.15, technical reports shall be prepared by or under the direction of appropriately qualified professional(s). Each technical report submitted shall contain a statement of qualification of the responsible licensed professional(s) as well as the professional's signature and/or stamp of the seal.

7. As specified in Standard Provision F.14, the Discharger shall comply with Electronic Submittal of Information (ESI) requirements by submitting all correspondence and reports required under MRP R7-2021-0023 and any future revision(s) hereto, including groundwater monitoring data and discharge location data (latitude and longitude), correspondence, and PDF monitoring reports to the State Water Board's Geotracker database. Documents too large to be uploaded into Geotracker should be broken down into smaller electronic files and labelled properly prior to uploading into Geotracker.

EXECUTIVE SUMMARY

Big Bear Lake is an important natural resource that provides extensive recreational, economic, ecological, and aesthetic benefits for the local community as well as the larger inland Southern California region. As with all other natural and man-made lakes in Southern California, the lake is subject to dramatic variability in water surface elevation; surface elevations reached as low as -48.5 feet (ft) relative to dam crest (72.33 ft maximum depth) in November 1961, corresponding to a volume of less than 1,000 acre-feet (af) and a lake surface area on the order of 200-300 acres during the extended drought in the late 1950's and early 1960's. Big Bear Municipal Water District (BBMWD) was subsequently formed in 1964 to manage and help stabilize the water level in Big Bear Lake. The region's natural hydrology includes severe protracted droughts and is influenced by the Pacific Decadal Oscillation (PDO) and El Nino-La Nina climate systems, which makes lake level stabilization a tremendous challenge. This wide variability in lake level, in turn, can have significant impacts on beneficial uses of the lake. Monitoring data collected primarily by the Big Bear City Community Services District (BBCCSD), BBMWD, and the Big Bear Lake Nutrient Total Maximum Daily Load (TMDL) group over the past decade underscore both the variability in regional hydrology and lake levels, and the consequences of extended periods of low runoff on water quality conditions. To minimize the impacts of frequent droughts, Replenish Big Bear was developed to recover and use a water resource currently discharged outside of the watershed.

This study assessed the overall conditions, ecological health and water quality in Big Bear Lake, and evaluated the potential influence on lake health of Replenish Big Bear. Three treatment alternative strategies (Treatment Alternatives), composed of advanced nutrient removal and reverse osmosis (RO) technologies, were evaluated:

(i) Alternative 1: TIN & TP Removal
(ii) Alternative 2: 70% RO (in addition to TIN & TP Removal)
(iii) Alternative 3: 100% RO (in addition to TIN & TP Removal)

This study included an analysis of available water quality data, development of a 2-D hydrodynamic-water quality model (CE-QUAL-W2), and application of the model to evaluate lake conditions with Replenish Big Bear that focused on the period from 2009-2019. This period was selected based upon a number of factors, including the wide range of hydrologic and water quality conditions in the lake, and availability of extensive lake monitoring and meteorological data, as well as some watershed monitoring data. Model simulations from 2020-2050 were also conducted to assess possible future conditions in Big Bear Lake under different hydrologic scenarios and Replenish Big Bear discharge alternatives. The routing of Replenish Big Bear water through Stanfield Marsh was also explored in greater detail to provide better understanding of the possible role of the marsh in nutrient attenuation.

Analysis of Water Quality Data

To augment the water quality information provided in the TMDL annual reports, additional conventional statistical and advanced machine learning analyses were conducted. Analyses focused on chlorophyll-a as the key response variable. The ratio of total nitrogen (total N) to total phosphorus (total P), often used to identify nutrient limitation, confirm P-limitation principally in place regulating algal production. Correlations developed between total P, total N, total inorganic N (TIN) and chlorophyll-a for each of the 4 TMDL sampling stations (n=150 for each station) indicate relatively weak correlations with nutrient concentrations (e.g., R^2-values of 0.08, 0.19, 0.21 and 0.31 between chlorophyll-a and total P for TMDL stations #1, 2, 6 and 9, respectively). R^2 values quantify the variance in dependent variable (chlorophyll-a) captured with the independent variable (e.g. total P), so it is clear that phytoplankton levels are a more complex function of conditions in the lake. Slightly higher R^2 values were in fact noted with total N (R^2=0.22-0.53), while chlorophyll-a was uncorrelated with TIN. Concentration of chlorophyll-a was also relatively weakly correlated with TDS and lake level; multiple linear regression (MLR) using all these variables yielded R^2-values of 0.31-0.55 depending upon TMDL sampling station.

Since significant portions of variance in observed chlorophyll-a concentrations remained uncaptured using MLR, machine learning was also evaluated. Machine learning, which is starting to be used in water quality applications, is often able to more effectively elucidate trends in complex datasets. Random forest and gradient-boosted regressor algorithms applied to TMDL station #1 data using day of year, lake level, TDS concentration and windspeed were able to capture most (0.92-0.96) of the observed variance in chlorophyll-a for the 10-yr 2009-2018 training set, notably without considering concentrations of total N or total P. For comparison, MLR using this same set of independent variables captured 0.43 of variance in observed chlorophyll-a concentrations. The gradient-boosted regressor model also demonstrated strong forecasting power, capturing 0.73 of variance in predicted chlorophyll-a concentrations of the 2019 data set (compared with 0.36 for the equivalent MLR model). Statistical analyses highlighted that multiple factors regulate chlorophyll-a concentrations in complex ways; machine learning was able to identify relationships and develop regressor models that reproduced and forecasted concentrations of chlorophyll-a with considerable accuracy.

Water column profile data were also used to quantify rates of internal nutrient recycling and areal hypolimnetic oxygen demand (AHOD). Internal nutrient recycling rates have been measured on a limited number of dates since 2002 using the laboratory core-flux method, while AHOD has not previously been measured at the lake. The *in situ* hypolimnetic mass balance approach using measured water column concentrations of ammonium as N (NH_4-N) and orthophosphate as P (PO_4-P) yielded recycling rates for 2010-2011 and 2015-2017 that were similar to previously measured values confirming the importance of nutrient recycling in lake biogeochemistry and nutrient budgets, and establishing the reliability of alum treatments in suppressing PO_4-P release. The analysis also yielded *in situ* estimates of early summer AHOD rates at TMDL station #1 of approximately 0.5 $g/m^2/d$.

Development of 2-D Hydrodynamic-Water Quality Model

A 2-D (longitudinal-vertical) hydrodynamic -water quality model for Big Bear Lake was developed using CE-QUAL-W2. The model quantifies heat and water budgets, 2-D hydrodynamics, and predicts concentrations of nutrients, dissolved oxygen (DO), chlorophyll-a and other parameters. The 2-D (longitudinal-vertical) representation assumes the primary gradients in water column properties and water quality are in the vertical and longitudinal directions, and well-mixed in the lateral direction; model branches were added for embayments that allow a quasi-3-D representation of the lake. The model requires extensive bathymetric, hydrologic, meteorological, water quality, and other data. The 2-D laterally-averaged model grid was developed from the bathymetric survey data collected by Fugro Pelagos Inc. (2006). Hydrologic data defining inflows, outflows, and withdrawals were developed from annual Big Bear Water Master reports. Hourly meteorological conditions were taken from Big Bear Airport and California Irrigation Management Information System (CIMIS) Station #199 located at the golf course. Data included solar shortwave radiation, air temperature, dewpoint temperature, windspeed, wind direction and cloud cover. Cloud cover was determined from sky cover conditions reported in METAR data for the airport. The model was calibrated against measured lake level, *in situ* profiles of temperature and DO, and laboratory analyses of water samples collected at the lake for 2009-2019. The model was first developed and calibrated for lake level, water column temperature profiles and TDS, where generally very good agreement was achieved (mean absolute errors of 3.6 cm, 0.79-0.89 °C, and 11.9 mg/L, respectively).

Following this, model calibration to water quality data was conducted. The model included external nutrient loading from the watershed, atmospheric deposition, internal nutrient recycling, and nutrient uptake and release associated with macrophyte and epiphyton growth, senescence and death. Two algal groups were simulated, included one representing cyanobacteria capable of N_2-fixation. The 1^{st}-order dynamic sediment model was combined with the 0^{th}-order SOD model to simulate nutrient recycling and DO uptake in the surficial bottom sediments. Relative root mean square error was 17.7% for total P, 18.0% for total N, 29.5% for TIN, and 24.0 % for chlorophyll-a. Mean absolute errors for DO ranged from 1.02 – 1.40 mg/L for the 4 TMDL sampling stations.

Application of Model to Evaluate Conditions with Replenish Big Bear

The model was then used to predict conditions in Big Bear Lake from 2009-2019 that would reasonably be expected with water from Replenish Big Bear delivered to the lake. Supplementation of natural flows with 1,920 af/yr of Replenish Big Bear water adds about 0.2 meter (m) annually to the lake relative to levels observed in 2009-2019 (baseline), and which accrues over time such that the lake was predicted to be 1.7 m higher in late 2018 compared to the level present at that time. Supplementation also increased predicted lake volumes and surface areas, with lake area about 300 acres (16%) larger in late 2018 compared with actual area (approximately 2,200 acres vs 1,900 acres, respectively). TDS levels in the lake were strongly influenced by level of treatment and TDS concentrations in the Replenish Big Bear water; Alternative 1 water with TIN and total P removal was projected to have a TDS of 450 mg/L, while addition of RO to further treat 70% and 100% of the water (Alternatives 2 and 3) was assumed

to reduce effluent TDS to 150 and 50 mg/L, respectively. Addition of 1,920 af/yr of Alternative 1 water significantly increased TDS levels in the lake, increasing average predicted TDS from 251 mg/L for the baseline (natural) condition for 2009-2019 to 300 mg/L, while Alternatives 2 and 3 were predicted to yield lower average TDS concentrations of 244 and 226 mg/L, respectively. Exceedance of the TDS water quality objective of 175 mg/L was predicted to occur 97.6% of the time for both the baseline condition and for Alternative 2, while exceedance frequency increased to 100% for Alternative 1 and was reduced to 93.3% for Alternative 3.

Nutrient concentrations in the Replenish Big Bear water also varied markedly with treatment, with total N and total P concentrations in Alternative 1 effluent being about 6-9 times higher than median watershed concentrations, while effluent concentrations in Alternative 2 were projected to be 1.8-2.3 times larger and Alternative 3 being about 0.4-0.8 times that of median watershed values. The increased nutrient loading from Alternative 1 had a strongly detrimental effect on water quality, increasing average concentrations over 2009-2019 baseline of total N by about 50%, total P by 70%, and chlorophyll-a by 300%. In comparison, further treatment of effluent with RO yielded average concentrations comparable to (Alternative 2) or slightly improved (Alternative 3) relative to the baseline (natural no-project) condition.

Predicted Long-Term Future Conditions with Replenish Big Bear

Simulations for 2009-2019 were extended to 2050 to evaluate possible long-term conditions in the lake under natural hydrologic variability with and without supplemental water from Replenish Big Bear. Since detailed meteorological and hydrological conditions for the future are not known *a priori*, existing meteorological and flow data for 2009-2019 were used as the basis for forecasts. 2009-2019 included extreme ranges in rainfall, runoff and air temperatures; assuming this range is broadly representative of likely future meteorological and hydrologic conditions, Monte Carlo techniques were used to randomly select 100 different 30 year annual records from this set of data. From these 100 different hydrologic scenarios, the 5^{th}-, 50^{th}- and 95^{th}-percentile 30 year average annual flow records and corresponding meteorological conditions were used as temporal boundary conditions for predictions of future conditions in the lake. The 5^{th}-percentile corresponds to an average inflow rate of 8,646 af/yr and represents extended drought, while the 50^{th}-percentile (median) corresponds to intervals of high runoff and drought (average annual inflow of 10,595 af/yr) comparable to 2009-2019, and the 95^{th}-percentile represents a period of protracted above average rainfall and runoff (average annual inflow of 12,225 af/yr). (Note that since precipitation and runoff are log-normally distributed, the above arithmetic mean values understate the range in runoff within the simulation intervals; that is, a single high runoff year can significantly skew upward average values during a period of protracted drought.)

Supplementation with Replenish Big Bear was also predicted to increase average long-term (2009-2050) conditions in the lake that varied under the 3 hydrologic scenarios. Under the 50^{th}-percentile hydrologic scenario, Replenish Big Bear was predicted to increase average lake level by 1.5 m, lake volume by nearly 13,000 af, and lake area by 260 acres relative to the predicted long-term baseline (no-project) condition. Water quality varied with level of treatment, with Alternative 1 nearly doubling predicted long-term average concentrations of TDS, total P and

total N and quadrupling average predicted chlorophyll-a levels. Long-term simulations indicate slight increases in average TDS, total P and total N and modest increase in chlorophyll-a for Alternative 2, and generally slight reductions or no significant change in concentrations with Alternative 3. Supplementation was predicted to have more substantial effects under the 5th-percentile runoff scenario, with increased average lake level of 3.4 m, increased volume of 16,104 af, and an additional average 638 surface acres (about 40% increase) relative to baseline. As with the median runoff scenario, supplementation with Alternative 1 effluent substantially degraded water quality, while further treatment (Alternatives 2 and 3) was predicted to result in comparable or slightly improved water quality in the lake. Effects of Replenish Big Bear were more muted at the 95th-percentile runoff scenario, when supplementation is less important, owing to the lower overall contributions of water and TDS and nutrients relative to the watershed.

Routing of Supplemental Water Through Stanfield Marsh

Simulations with Replenish Big Bear involved routing of effluent through Stanfield Marsh, where some nutrient uptake could be expected. Simulations indicate net removal of total P through the Marsh with Alternative 1 and Alternative 2 effluent, while simulations predicted that the Marsh would be a modest source of total P to Alternative 3 water with very low influent concentrations. Interestingly, the Marsh was predicted to be a source of total N across all levels of treatment, due to sediment decay, and some N_2-fixation and subsequent decay in response high PO_4-P concentrations and high TN:TP ratios in the effluent. Further work is needed, however, to better understand the role of the Marsh as a net sink and/or source for nutrients.

Summary

Lake conditions and water quality in Big Bear Lake varied significantly over 2009-2019, with wide variations in lake level, volume and surface area, as well as concentrations of TDS, nutrients and chlorophyll-a. Statistical, machine learning and hypolimnetic mass balance analyses provided valuable new information about water quality in Big Bear Lake, while CE-QUAL-W2 was able to reproduce observed trends in lake conditions. Supplementation of natural runoff with Replenish Big Bear water significantly increased lake levels, volumes and surface areas, especially during periods of drought, with resulting recreational, aesthetic, community and related benefits. The level of treatment had dramatic effects on water quality, however. Nutrient removal (Alternative 1) was not sufficient to protect water quality, although nutrient removal with further treatment (Alternatives 2 and 3) was predicted to yield water quality comparable to or slightly improved relative to baseline conditions.

I. INTRODUCTION AND STUDY OBJECTIVES

The Replenish Big Bear Team, a collaborative regional water resources program being implemented by Big Bear Area Regional Wastewater Agency (BBARWA), Big Bear City Community Services District (BBCCSD), Big Bear Lake Department of Water and Power (BBLDWP), Big Bear Municipal Water District (BBMWD) and the Bear Valley Basin Groundwater Sustainability Agency (BVBGSA), engaged Professor Emeritus Michael A. Anderson (Dr. Anderson), who has in-depth knowledge of the Big Bear Lake (Lake), to evaluate the Lake water quality conditions and assess the potential impacts of the Replenish Big Bear project. This study was prepared in response to the Santa Ana Regional Water Quality Control Board (Santa Ana Water Board) staff's need to have a better understanding of the Lake's health to consider approving a discharge above current Basin Plan water quality objectives (WQOs) or the Nutrient Total Maximum Daily Load (Nutrient TMDL) for Dry Hydrologic Conditions.

This study assesses the overall conditions, ecological health, and water quality in Lake, and evaluates the potential influence on lake health of three treatment alternative strategies (Treatment Alternatives) to supplement the natural water supply to the lake. These Treatment Alternatives are composed of advanced nutrient removal and reverse osmosis (RO) technologies:

(i) Alternative 1: TIN & TP Removal
(ii) Alternative 2: 70% RO(70% RO + 30% TIN & TP Removal)
(iii) Alternative 3: 100% RO

A. Project Background

Replenish Big Bear was developed in an effort to help protect Big Bear Valley (Valley) and the Santa Ana Watershed from the impacts of drought and variable precipitation by recovering a water resource currently discharged outside of the watershed. Replenish Big Bear is comprised of three independent projects, which will be implemented separately in the following progression, as practicable:

- Effluent discharge to Stanfield Marsh (and subsequently to the Lake) and Shay Pond;
- Use of Lake water for landscape irrigation of the local golf course; and
- Use of Lake water for groundwater recharge in Sand Canyon.

The first project, and primary regulatory driver, includes treatment upgrades at the BBARWA wastewater treatment plant (WWTP) to produce highly treated effluent for discharge to Shay Pond and Stanfield Marsh, which flows into the lake. This study evaluates the water quality in the lake and assesses impacts of discharge through Stanfield Marsh. For redundancy purposes, BBARWA is also seeking to maintain its current discharge location in Lucerne Valley, where undisinfected secondary effluent is currently conveyed to irrigate crops used for livestock feed. These new discharge points will allow BBARWA to minimize discharge of treated effluent outside of the watershed, which will increase Lake levels to better support beneficial uses including recreation and habitat, particularly in times of drought. Additionally, discharge to Shay Pond will replace potable water currently discharged to maintain the water flow through the pond. Figure

1 shows the project components for this first project, which is referred to as the effluent discharge project.

The other two projects will utilize lake water for (i) landscape irrigation at the local golf course to achieve in lieu recharge of the groundwater basin and (ii) direct groundwater recharge in Sand Canyon. These projects are not planned for any time soon.

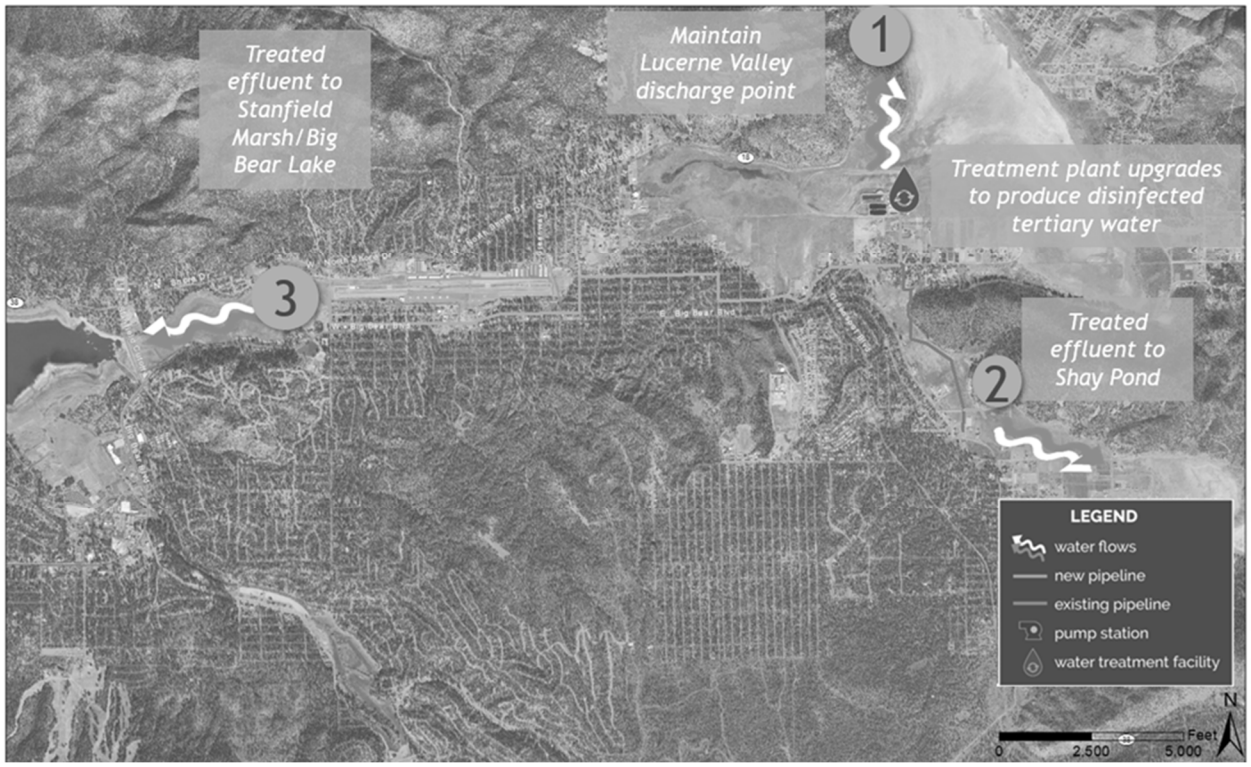

Figure 1. Effluent discharge project components and overview of discharge locations

B. Lake Background

Big Bear Lake is an important resource that provides extensive recreational, economic, ecological, and aesthetic benefits for the local community as well as the larger inland southern California region. Together, Stanfield Marsh and the Lake have a surface area of nearly 3,000 acres, a storage capacity of 73,320 af, and an average depth of 32 feet (ft). Stanfield Marsh and the Lake are both waters of the State of California (State) and United States (U.S.), which have several designated beneficial uses. For reference, Table 1 shows the designated beneficial uses of the Lake and Stanfield Marsh per the 1995 Water Quality Control Plan for the Santa Ana Basin Plan (Basin Plan), as amended in 2008, 2011, 2016, and 2019. In addition, the Nutrient TMDL was adopted to address concerns with phosphorus and nitrogen impacts on the lake. Table 2 presents the Lake regulatory limits set to protect the Lake benefits.

Table 1. Beneficial uses of Big Bear Lake and Stanfield Marsh		
Beneficial Uses	**Big Bear Lake**	**Stanfield Marsh**
AGR - Agricultural Supply	✓	
COLD - Cold Freshwater Habitat	✓	✓
GWR - Groundwater Recharge	✓	
MUN - Municipal and Domestic Supply	✓	✓
RARE - Rare, Threatened, or Endangered Species	✓	✓
REC1 - Water Contact Recreation	✓	✓
REC2 - Non-Contact Water Recreation	✓	✓
SPWN - Spawning, Reproduction, and/or Early Development	✓	
WARM - Warm Freshwater Habitat	✓	
WILD - Wildlife Habitat	✓	✓

Total Nitrogen (TN) (mg/L-N)		1
Chlorophyll-a (µg/L)		14
Note: **Bolded** constituents were identified as priority in previous regulatory meetings and are specifically evaluated in this study.		

The Lake is located about 6,743 ft (2,055 m) above mean sea level (MSL) in the San Bernardino Mountains in San Bernardino County. The Lake was formed following construction of the Bear Valley Dam in 1883-1884 to serve as an irrigation supply for the citrus industry in the downstream Redlands-San Bernardino communities. Since that time, the Lake has served as a vital engine for economic growth in the Valley, and the region has developed into a year-round destination with extensive recreational and commercial activities, primary and secondary residences, vacation properties and hospitality, and other services.

As with all other natural and man-made lakes in Southern California, the Lake is subject to dramatic variability in water surface elevation; surface elevations reached as low as -48.5 ft relative to dam crest (72.33 ft maximum depth) in November 1961, corresponding to a volume of less than 1,000 af and a lake surface area on the order of 200-300 acres during the extended drought in the late 1950's and early 1960's. BBMWD was subsequently formed in 1964 to manage and help stabilize the water level in the Lake. The region's natural hydrology includes severe protracted droughts and is influenced by the Pacific Decadal Oscillation (PDO) and El Nino-La Nina climate systems (Kirby, 2010), which makes lake level stabilization a tremendous challenge.

This wide variability in Lake level, in turn, can have dramatic impacts on recreational, economic, and aesthetic values of the Lake, as well as ecological conditions and Lake water quality.

Monitoring data collected over the past decade underscore both the variability in regional hydrology and Lake levels, and the consequences of extended periods of low runoff for water quality conditions in the Lake.

C. Objectives

This study (i) analyzed available historical data on Lake conditions to improve quantitative understanding of water quality in the Lake and the interactions and relationships of key causal and response parameters through statistical and advanced machine learning approaches; (ii) developed and calibrated a 2-D hydrodynamic-water quality model using available historical data to develop an improved process-level understanding of water quality; (iii) assessed conditions in the Lake under natural variable hydrology and climate change through the application of the 2-D hydrodynamic water quality model; and (iv) evaluated, through model simulations, Lake conditions with different treatment alternatives for the proposed Replenish Big Bear project. Phosphorus, nitrogen and total dissolved solids (TDS) are the primary constituents of interest with respect to impacts to the Lake and its beneficial uses.

II. ANALYSIS OF AVAILABLE WATER QUALITY DATA

As illustrated in the Baseline Assessment Tech Memo (WSC, 2020), the Lake is subject to widely varying lake volumes and wide ranges in nutrient, TDS, and chlorophyll-a concentrations. Extension of the analysis provided in the Baseline Assessment Tech Memo (WSC, 2020) was conducted to include additional calculations, regressions, and machine learning to better understand the factors, relationships, and interactions governing water quality. Field and laboratory data for TMDL stations #1 (Dam), #2 (Gilner Point), #6 (Mid-lake) and #9 (Stanfield) over the 2009-2019 time period formed the basis for the analyses. These monitoring stations are shown in Figure 2.

Linear regressions and other statistical analyses are commonly used to identify factors affecting water quality in lakes. Machine learning is now starting to be used for water quality assessments (Chou et al., 2018; Ahmed et al., 2019), including short-term forecasting of algal blooms (Park et al., 2015), owing its ability to often elucidate relationships within complex datasets. Supervised machine learning requires a robust dataset on which to train and validate models. BBMWD has developed and maintained a high quality Lake monitoring program, and has an excellent dataset that was used to train and test different supervised machine learning models. This dataset provides an empirical, data-based approach to identifying and understanding relationships between causal and response variables and predicting water quality in the Lake.

Data were also used where possible to quantify rates of important processes operating within the Lake. For example, increases in total P and total inorganic nitrogen (TIN) concentrations are routinely recorded in late summer/early fall that are thought to be associated with lake mixing (WSC, 2020). Hypolimnetic and/or water column mass balance calculations often allow calculation of internal nutrient recycling rates from bottom sediments (Cooke et al., 2005). Such calculations also provide comparisons with previous laboratory core-flux measurements (Anderson and Dyal, 2003), and allow evaluation of effects of runoff, lake level, and other factors on internal nutrient loading, which is recognized as an important source of nutrients to the Lake (contributing, for example, an estimated 52% of total nitrogen and total P loading under a dry scenario) (Santa Ana Water Board, 2005).

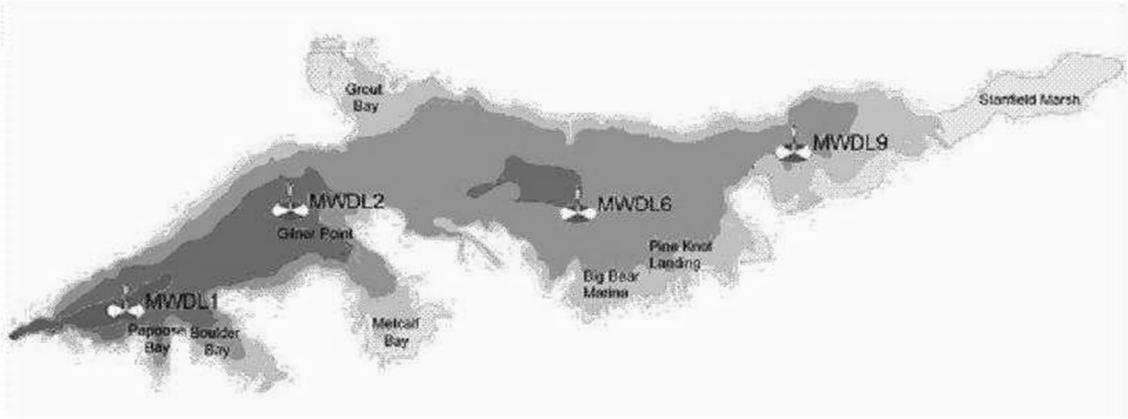

Figure 2. Big Bear Lake TMDL sampling station.

A. Factors Regulating Algal Productivity in Big Bear Lake

1. Statistical Analysis

The TMDL annual water quality reports provide water quality reports, time-series data, and summary statistics, so this section focuses on select statistical analyses of TMDL water quality data. The Lake is generally considered to be P-limited; the ratio of TN to TP concentrations (TN:TP ratio) is reflective of the elemental composition of phytoplankton, with P-limitation generally recognized at TN:TP ratios >20, and N-limitation at TN:TP ratio <5 (Thomann and Mueller, 1998). Photic zone TN and TP concentrations for the 2009-2019 time period were used to calculate TN:TP ratios at the four stations to confirm that P-limitation typically exists in the Lake. Median TN:TP ratios were 27-28 at the Dam, Gilner Point, and Mid-lake stations, but somewhat lower (21.1) at the Stanfield station (Table 3). The TN:TP ratios exhibited considerable variability, so values have been plotted as cumulative distribution functions (Figure 3). Based on these data, the Lake can be considered to be P-limited about 70% of the time and co-limited about 30% of the time. By this measure, N-limitation was present only 1-2% of the time, thus supporting efforts to constrain external loading and internal recycling of P in the Lake.

Table 3. Summary statistics for total nutrients and chlorophyll-a concentrations at the four TMDL sampling stations for 2009-2019 (photic zone).

Parameter	Value	Dam	Gilner Point	Mid-Lake	Stanfield
Total P	Median	0.036	0.040	0.040	0.051
	25-75%	0.024 – 0.050	0.024 – 0.060	0.026 – 0.068	0.033 – 0.088
	Min-Max	0.005 – 0.150	0.005 – 0.210	0.005 – 0.200	0.008 – 0.400
Total N	Median	1.12	1.10	1.16	1.22
	25-75%	0.92 – 1.26	0.93 – 1.27	0.94 – 1.33	0.96 – 1.53
	Min-Max	0.028 – 2.14	0.19 – 3.25	0.17 – 2.43	0.28 – 2.89
Chlorophyll-a	Median	9.4	10.9	11.7	15.1
	25-75%	6.1 – 14.6	6.7 – 16.0	7.5 – 16.5	8.8 – 27.0
	Min-Max	0.9 – 51	0.5 – 205	2.0 – 106	1.8 – 150
TN:TP	Median	28.2	27.3	27.2	21.2
	25-75%	19.1 – 40.4	18.9 – 38.2	17.4 – 39.0	14.8 – 30.8
	Min-Max	7.3 – 162	3.4 – 244	4.0 – 284	3.5 – 147

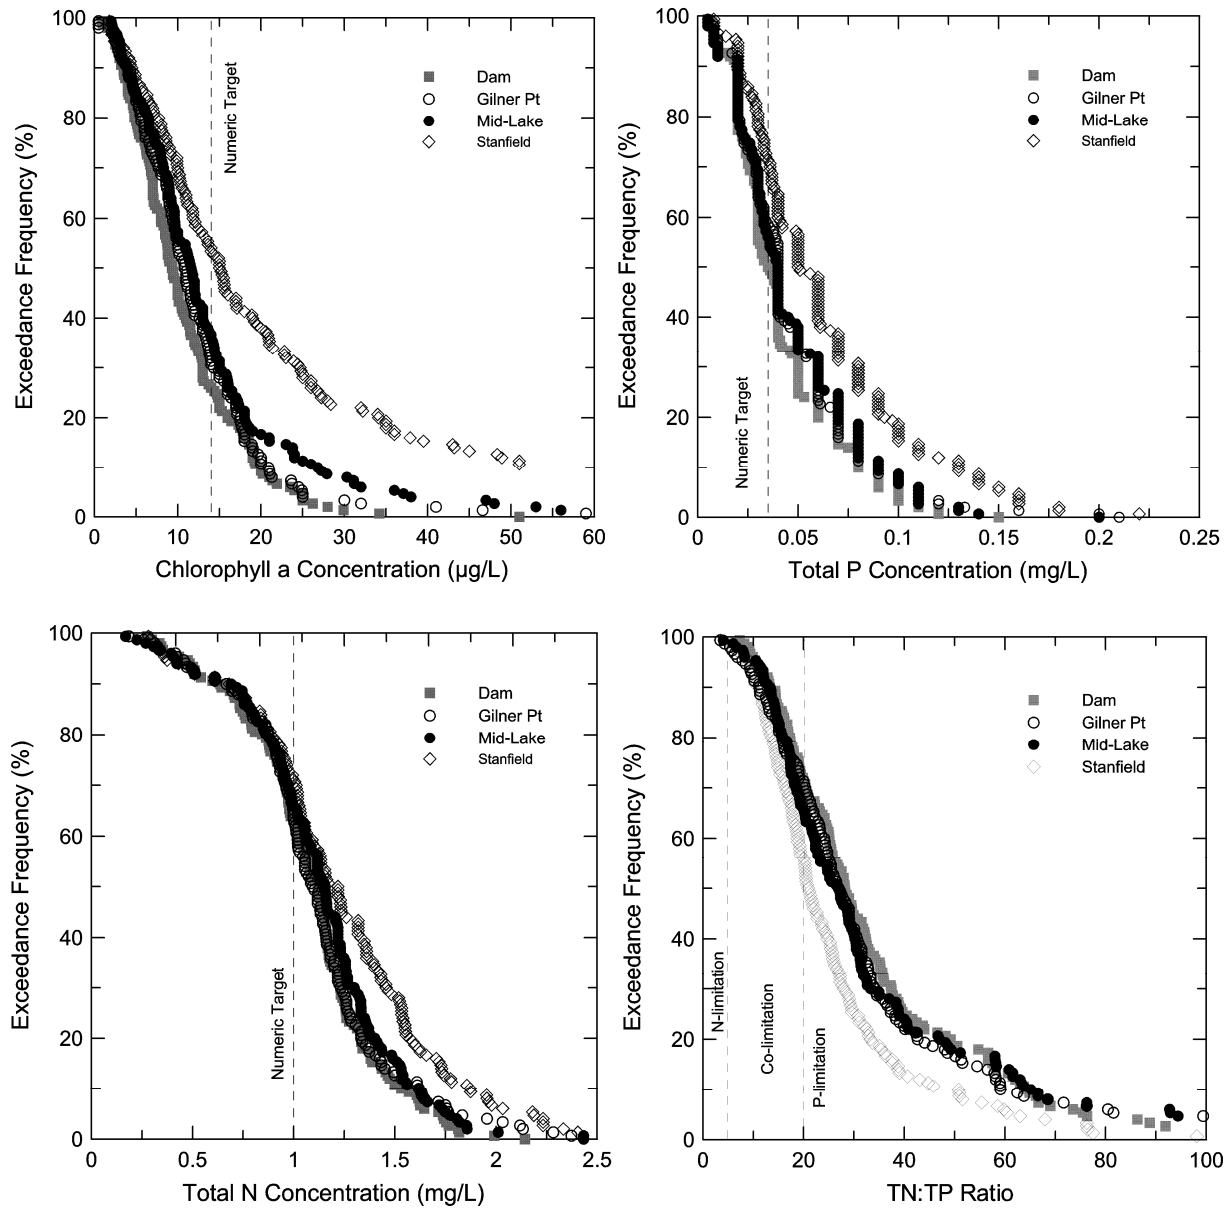

Figure 3. Cumulative distribution functions for a) chlorophyll-a, b) total P, c) total N and d) TN:TP ratios for the 4 TMDL sampling stations.

Correlations between chlorophyll-a concentrations and selected water column properties indicate that no single property captures a substantial amount of the variance in observed chlorophyll-a concentration for all four sampling stations, although the Stanfield station was somewhat more responsive to nutrient concentrations than the other stations (Table 4). Interestingly, TP concentration captured a smaller fraction of observed chlorophyll-a variance than TN (0.08-0.31 vs 0.22-0.53, respectively). Depth below full pool appears to be a useful attribute that integrates across a number of lake conditions and captured, on average, slightly more of the variance (larger R^2) in chlorophyll-a concentrations across all sites (R^2 = 0.22) compared with TP (R^2=0.21) (Table 4). Multiple linear regression using all of these parameters yielded limited improvements in R^2 values compared with single values, indicating that a substantial amount of variance in chlorophyll-a concentration is unaccounted for using basic water quality (and lake level) information (Table 4). Results are very similar when considering only summer months (Jun-Sep) (data not shown). In general, there was no strong correlation between chlorophyll-a and the parameters evaluated.

Table 4. R^2-values for correlations between selected water column properties and chlorophyll-a concentrations (Zrel full represents depth below full pool) (n=150).

Station	**TN**	**TP**	**TIN**	**TDS**	**$Z_{rel\ full}$**	**All**
Dam	0.22	0.08	0.05	0.17	0.29	0.31
Gilner Pt	0.31	0.19	0.00	0.25	0.32	0.43
Mid-Lake	0.34	0.21	0.00	0.19	0.25	0.40
Stanfield	0.53	0.31	0.04	0.18	0.22	0.55

Plots for Gilner Point highlight the variability in chlorophyll-a concentrations as a function of TP, TN, and TDS concentrations and depth below full pool ($Z_{ref\ full}$) across the wide ranging conditions present in the Lake over the 2009-2019 period (Figure 4).

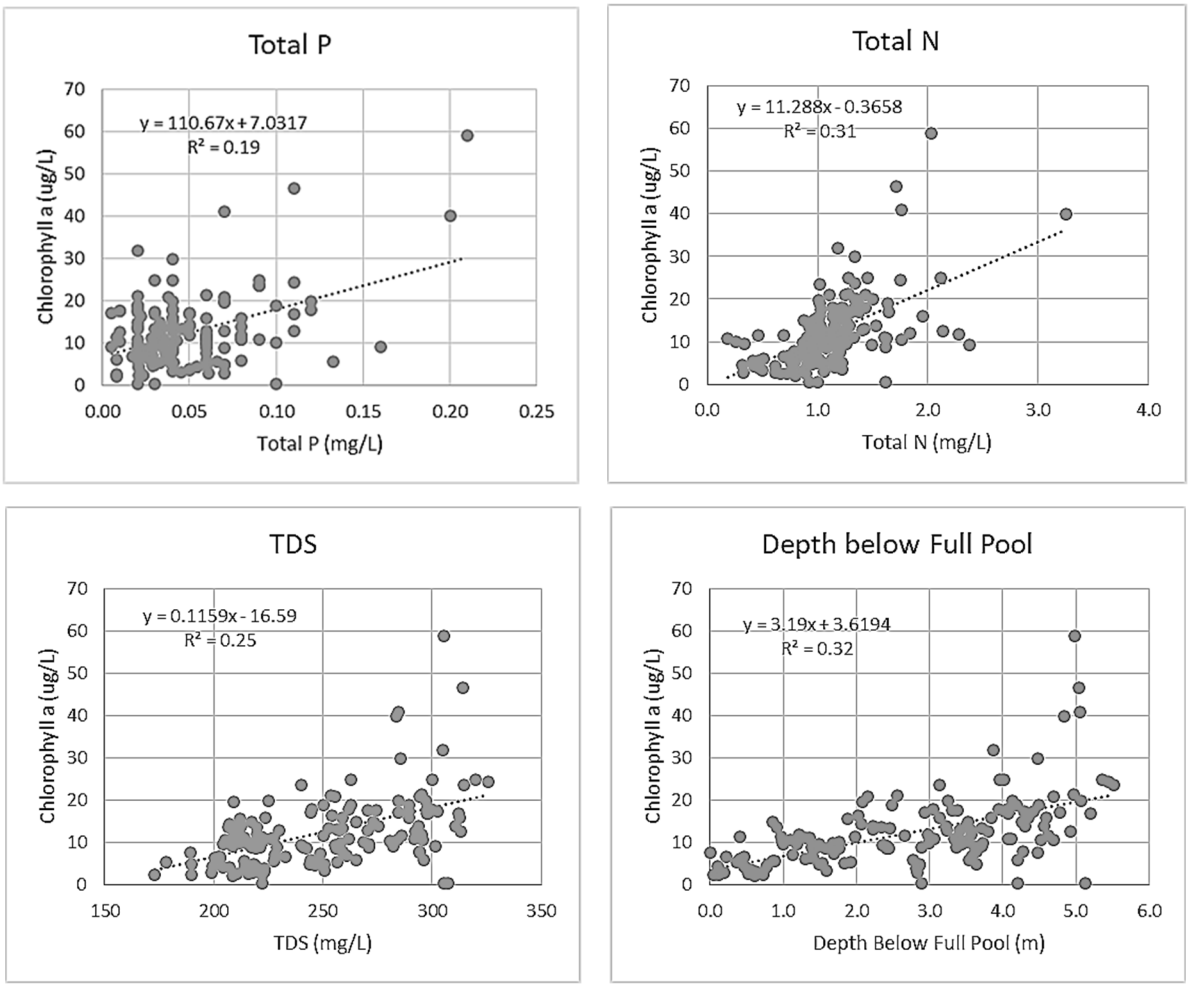

Figure 4. Plots and regression lines between chlorophyll-a and a) total P, b) total N, c) TDS and d) depth below full pool (TMDL station #2, Gilner Point).

2. Machine Learning

Linear regression equations reflected general trends indicating increases in chlorophyll-a in response to increased concentrations of nutrients, TDS, and decreasing lake level, but only captured a relatively small proportion of the variability in measured chlorophyll-a concentrations. Machine learning is often able to more effectively elucidate trends in complex datasets. Random forest and gradient boosted regression trees, k-nearest neighbor, and neural net models were developed using Python 3.7 scikit-learn (e.g., Mueller and Guido, 2017). The machine learning algorithms were trained on the 10-yr record from 2009-2018 (inclusive) and then used to predict water quality for 2019 for comparison with observed conditions.

Chlorophyll-a was the target variable in the machine learning analysis since it represents the key response variable for water quality in the Lake. Independent variables ("features") evaluated included total and dissolved N and P concentrations, water temperature, day of year, lake level

(depth below full pool), TDS concentration, and wind speed (U_w). Model goodness-of-fit was determined based on mean absolute error (MAE) and variance captured. Interestingly, nutrient concentrations and water temperature contained less value in predicting chlorophyll-a concentrations than day of year, lake level, TDS, and average wind speed. The relationships between these features and chlorophyll-a concentration at TMDL Station #1 (dam) in the training data are graphically represented in Figure 5.

The lowest set of panels in the following matrix diagram are scatter plots of chlorophyll-a (Chl) as a function of day of the year (Day), lake level below full pool (Level), TDS, and average windspeed (Uw). Visually one notes that chlorophyll-a exhibits trends of increased concentrations with increasing depth below full pool and increased TDS, although extremely large variability in chlorophyll-a concentrations exists at any given value of lake level or TDS. The final panel on the lower right side of the figure represents a frequency histogram, illustrating that most chlorophyll-a values were around 5-10 µg/L (*i.e.*, below the TMDL target of 14 µg/L), with very few observations at this station >25 µg/L (Figure 5).

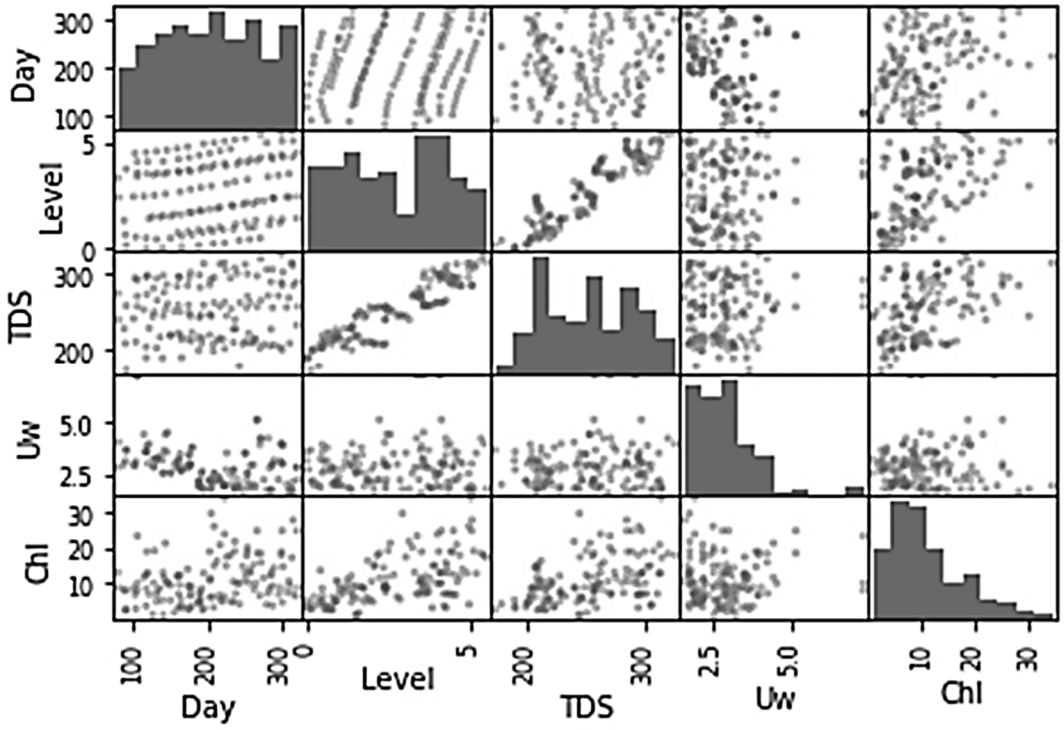

Figure 5. Matrix diagram showing scatter plots between selected parameters at TMDL station #1 (dam).

Application of the random forest regressor (RFR) and gradient-boosted regressor (GBR) using Day-Level-TDS-Windspeed as features yielded models that much more accurately reproduced observed chlorophyll-a concentrations and captured more than 90% of the variance (Figure 6, Table 5). Multiple linear regression using an expanded parameter set yielded a model that was

only better than the multi-layer perceptron (MLP) model, which actually generated excess variance.

Table 5. Mean absolute error between predicted and observed chlorophyll-a concentration and variance captured by machine learning and multiple linear regression models (2009-2018 training set).

Model (TMDL station #1)	**MAE (µg/L)**	**Variance Captured**
K-Nearest Neighbor (KNR)	3.4	0.52
Random Forest Regressor (RFR)	1.4	0.92
Gradient-Boosted Regressor (GBR)	1.0	0.96
Multi-Layer Perceptron (MLP)	14.8	-3.2
Multiple Linear Regression	3.3	0.43

The RFR and GBR models captured >90% of the variance in observed chlorophyll-a concentrations without incorporation of nutrient data (using only Day-Level-TDS-Uw), and mean absolute error (MAE) values were only about 30-40% that of the multiple linear regression model (Table 6).

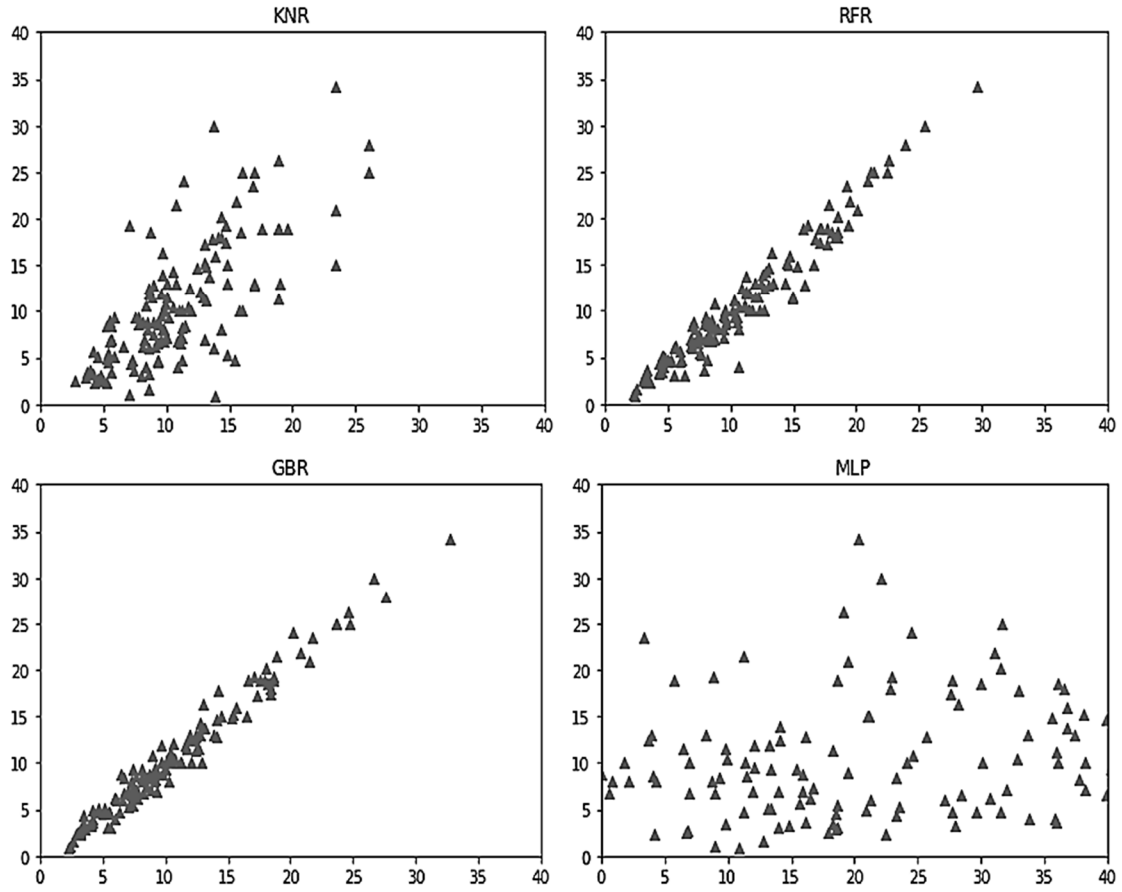

Figure 6. Scatter plots comparing predicted (x-axis) and observed (y-axis) chlorophyll-a concentrations using a) k-nearest neighbor regressor (KNR), b) random forest regressor (RFR), c) gradient-boosted regressor (GBR), and d) multi-layer perceptron (MLP) algorithms.

The RFR and GBR models had significant predictive power for 2019, capturing 58% and 73% of the variance in observed chlorophyll-a (compared with only 36% for the multiple linear regression model), although MAE values were much higher than the 2009-2018 training set. (For reference, a temperature-nutrient model captured <10% of variance in observed chlorophyll-a, underscoring the complex relationships governing algal productivity in the Lake.)

Table 6. Mean absolute error between predicted and observed chlorophyll-a concentrations and variance captured by machine learning and multiple linear regression models (2019 validation set).

Model (TMDL #1)	MAE (µg/L)	Variance Captured
Random Forest Regressor (RFR)	4.5	0.58
Gradient-Boosted Regressor (GBR)	5.9	0.73
Multiple Linear Regression	6.3	0.36

B. Internal Recycling and Hypolimnetic Mass Balance

Internal nutrient recycling is recognized as an important part of the nutrient budget of the Lake (Santa Ana Water Board, 2005). Ortho-phosphate-P (PO_4-P), sometimes also referred to as soluble reactive P (SRP), is released from bottom sediments via reductive dissolution of ferric iron-bound phosphate phases under anoxic conditions and through microbially-mediated dephosphorylation of organic matter. Similarly, NH_4-N is released from bottom sediments by deamination of organic matter. Under stratified conditions, PO_4-P and NH_4-N accumulate in the hypolimnion and their increase in concentrations allows calculation of *in situ* recycling rates.

Station #1 nearest the dam is the deepest of the four main sampling stations and is often observed to exhibit some thermal stratification during the spring through early-mid summer. One consequence of the development of thermal stratification is that nutrients released from sediments accumulate in the bottom waters and their concentrations increase over time, with NH_4-N and PO_4-P reaching, *e.g.,* up to 0.8 mg/L and 0.2 mg/L in the summer of 2010 (Figure 7).

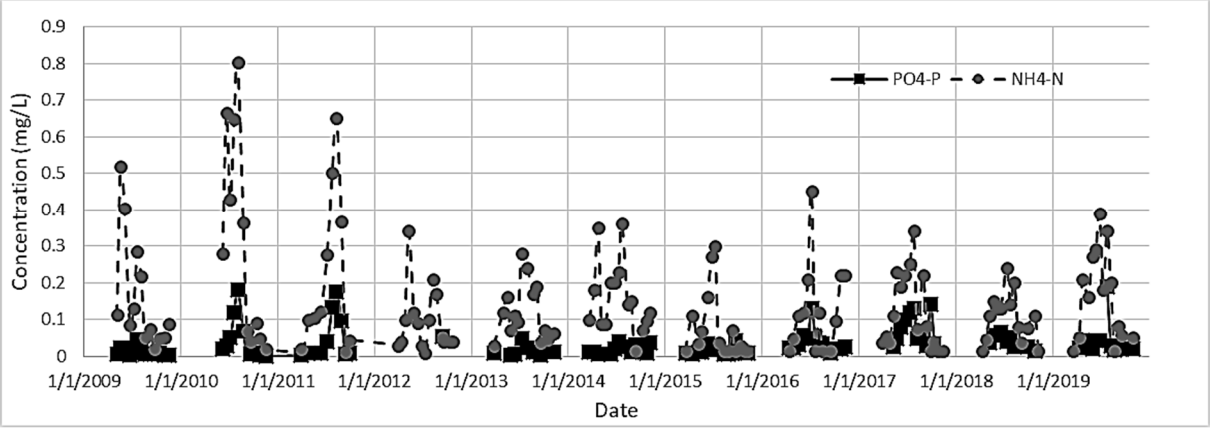

Figure 7. Concentrations of PO4-P and NH4-N in bottom water samples at TMDL station #1 (dam).

The concentrations in bottom waters tracked quite closely the magnitude of stratification, represented by △T (the difference in temperature between the 1 m and bottom depths) (e.g., Figure 8). That is, concentrations tended to increase with increasing △T, while mixing of the water column (△T near 0°C) was associated with sharp reductions in dissolved nutrients due to their mixing throughout the water column.

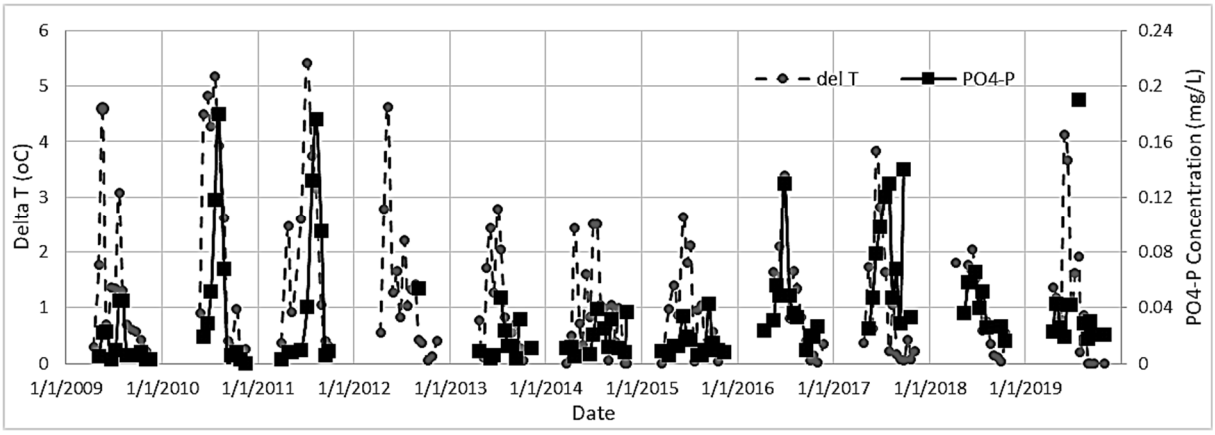

Figure 8. Relationship between bottom water PO_4-P concentrations and temperature difference between 1 m and bottom depths (△T or del T).

Stratification also results in widely-recognized loss of dissolved oxygen (DO), as aerobic bacteria consume DO; with DO unable to be replenished through exchange with the upper well-aerated mixed portion of the water column (epilimnion), oxygen demand quickly depletes DO in the hypolimnion, and is restored when the water column mixes later in the summer (Figure 9).

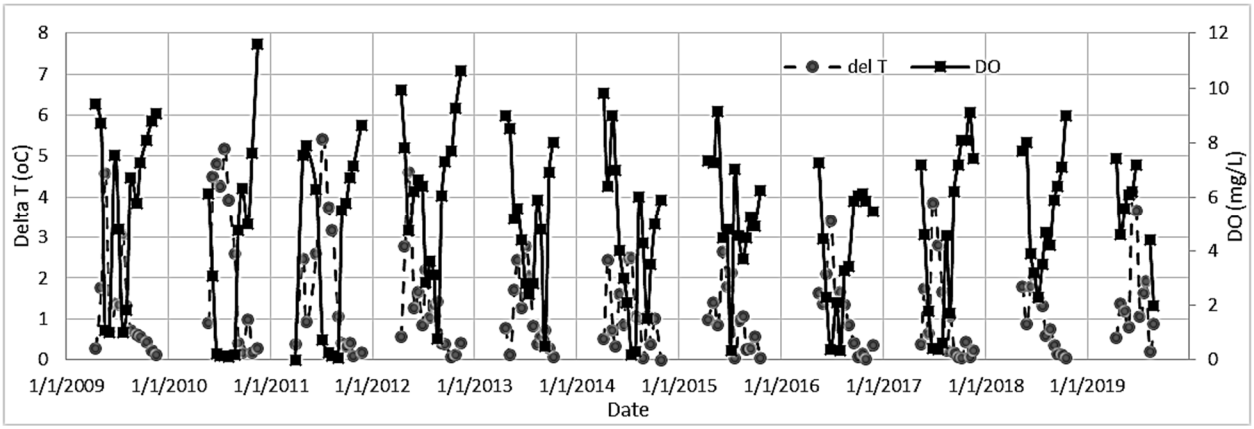

Figure 9. Relationship between bottom water DO concentrations and temperature difference between 1 m and bottom depths (△T or del T).

The increases over time in NH_4-N and PO_4-P and loss of DO (Figures 7-9) during periods of stratification (△T > 0.5 - 1°C) were used to calculate *in situ* internal recycling and areal hypolimnetic oxygen deficit (AHOD) at TMDL station #1 (Table 7). Included in this table are results from laboratory core-flux measurements in 2002-03 and following alum applications in 2004-06 and 2015 in which intact sediment cores were collected from the lake and incubated in the lab at temperature and DO conditions present at the time of sampling. Good agreement was found between 2002-03 laboratory and 2010-11 *in situ* PO_4-P flux values, while lower *in situ* values were found for NH_4-N flux. *In situ* estimates of PO_4-P flux preceding and following the 2015 alum application were in good agreement with pre- and post-laboratory core-flux incubations. AHOD

rates have not previously been measured in the Lake, so *in situ* calculations provide valuable new information about this important process. Moreover, i*n situ* AHOD values are consistent with the trophic state of the lake, and were reduced following the 2015 alum treatment. It should also be noted that similar PO_4-P and NH_4-N flux rates were measured in lab core-flux incubations following 2004 and 2015 alum treatments, indicating general reliability of alum treatments to inhibit PO_4-P release.

Table 7. Internal nutrient loading and areal hypolimnetic oxygen demand (AHOD) rates measured in laboratory and estimated from in situ hypolimnetic mass balance approach.

	Lab			*In Situ*	
Parameter	2002-03	2004-06 (post-alum)	2015 (post-alum)	2010-11	2015-17 (post-alum)
PO_4-P Flux ($mg/m^2/d$)	13.0 ± 2.8	3.3 ± 2.2	0.7 ± 0.2	15.9 ± 0.1	3.2 ± 1.0
NH_4-N Flux ($mg/m^2/d$)	92.6 ± 19.7	38.7 ± 2.7	40.3 ± 6.3	50.9 ± 10.4	26.0 ± 13.3
AHOD ($g/m^2/d$)	NA	NA	NA	0.46 ± 0.04	0.31 ± 0.05

Summary

To augment the water quality summaries provided in the TMDL annual reports, additional statistical and advanced machine learning analyses were conducted. Analyses focused on chlorophyll-a as the key response variable. The ratio of total N to total P), often used to identify nutrient limitation, confirm P-limitation principally in place regulating algal production. Correlations developed between total P, total N, TIN and chlorophyll-a for each of the 4 TMDL sampling stations (n=150 for each station) indicate relatively weak correlations with nutrient concentrations, so it is clear that phytoplankton levels are a more complex function of conditions in the lake. Multiple linear regression (MLR) using TN, TP, TIN, TDS and lake level yielded R^2-values of 0.31-0.55 depending upon TMDL sampling station.

Since significant portions of variance in observed chlorophyll-a concentrations remained uncaptured using MLR, machine learning was also evaluated. Random forest and gradient-boosted regressor algorithms applied to TMDL station #1 data using day of year, lake level, TDS concentration and windspeed were able to capture most (0.92-0.96) of the observed variance in chlorophyll-a for the 2009-2018 training set, notably without considering concentrations of total N or total P. For comparison, MLR using this same set of independent variables captured 0.43 of variance. The gradient-boosted regressor model also demonstrated strong forecasting power, capturing 0.73 of variance in predicted chlorophyll-a concentrations of the 2019 data set (compared with 0.36 for the equivalent MLR model). Machine learning was thus able to identify relationships and develop regressor models that reproduce and forecast concentrations with considerable accuracy.

Water column profile data were also used to quantify rates of internal nutrient recycling and AHOD. Internal nutrient recycling rates have been measured on a limited number of dates since 2002 using the laboratory core-flux method, while AHOD rates have not previously been measured at the lake. The *in situ* hypolimnetic mass balance approach using measured water

column concentrations of ammonium as N (NH_4-N) and orthophosphate as P (PO_4-P) yielded recycling rates for 2010-2011 and 2015-2017 that were similar to previously measured values confirming the importance of nutrient recycling in lake biogeochemistry and nutrient budgets, and establishing the reliability of alum treatments in suppressing PO_4-P release. The analysis also yielded *in situ* estimates of late spring-early summer AHOD rates at TMDL station #1 of approximately 0.5 $g/m^2/d$.

III. DEVELOPMENT OF 2-D HYDRODYNAMIC- WATER QUALITY MODEL FOR BIG BEAR LAKE

Numerical modeling with process-based models is routinely used to simulate historical/baseline and future conditions in lakes and reservoirs. Water quality models represent lake properties and processes through mathematical equations that can vary widely in their complexity, from simple 0-D models such as BATHTUB that involves basic mass balance calculations combined with empirical chlorophyll-a-nutrient responses (Walker, 1987), to highly complex 2-D models such as CE-QUAL-W2 (Wells, 2020) and 3-D hydrodynamic water quality models such as AEM3D (Hodges and Dallimore, 2014; Hipsey, 2014) that solve the Navier-Stokes equation and have highly complex sets of mathematical equations describing ecological interactions and water quality. Nonetheless, even with the most complex models, such models are inherently simplifications of lake ecosystems. The complexity of the model developed and its parameterization is also dependent upon the information available about the lake ecosystem. Big Bear Lake exhibits significant horizontal and vertical gradients in water quality and hydrodynamics, indicating that a 2-D laterally-averaged or 3-D representation of the lake is appropriate. Solution to the Navier-Stokes equation in 3-D is computationally extremely demanding, so 3-D hydrodynamic-water quality models are generally limited to relatively short-term simulation periods, often just months to a few years in duration, making calibration to and simulation of longer time periods often impractical. A 2-D laterally-averaged hydrodynamic-water quality model often provides sufficient resolution to capture longitudinal and vertical gradients in conditions, including local effects of inflows and outflows, while allowing for multi-year calibration of complex biogeochemical processes and simulations of decade-plus time scales.

A 2-D (longitudinal-vertical) hydrodynamic water quality model for Big Bear Lake was developed using CE-QUAL-W2 (Wells, 2018). The model was originally developed at the U.S. Army Corps of Engineers Waterways Experiment Station, extensively refined over time, and has been used for over 450 lakes and reservoirs, nearly 300 rivers, and numerous estuaries and other waterbodies (Wells, 2018). The model quantifies heat and water budgets, 2-D hydrodynamics, and predicts concentrations of nutrients, DO, chlorophyll-a, turbidity, and other parameters. The 2-D (longitudinal-vertical) representation assumes the primary gradients in water column properties and water quality are in the vertical and longitudinal directions, and well-mixed in the lateral direction; model branches can be added for embayments that allow a quasi-3-D representation of the lake. Advantages of CE-QUAL-W2 over the WASP model, which was used in early TMDL work (RWQCB, 2005), include the better spatial representation of the lake, hydrodynamic and water quality models are incorporated into a single model within CE-QUAL-W2, and it allows for multiple algal, macrophyte, and epiphyte species simulating their growth, respiration and mortality, and corresponding influence on nutrient cycling and other processes. CE-QUAL-W2 was recommended to replace the use of WASP in the 2010 TMDL Action Plan (Big Bear Lake TMDL Task Force, 2010).

A. Approach

Development and application of the model requires extensive bathymetric, hydrologic, meteorological, water quality, and other data. The model was developed focusing on the 2009-2019 time period. This period was selected based upon a number of factors, including the wide range of hydrologic and water quality conditions in the lake, and availability of extensive lake monitoring and meteorological data, as well as some watershed monitoring data. The 2-D laterally-averaged model grid was developed from the bathymetric survey data collected by Fugro Pelagos Inc. (2006), including the original dam, which was represented as an internal weir within the model. The model grid included 85 segments with 1 m vertical layers and 5 branches: branch 1, with 58 segments representing the main Lake spanning Stanfield Marsh to the Dam; and branches 2-5 representing Kidd Bay, Boulder Bay, Metcalf Bay and Grout Bay, respectively (Figure 10). Good agreement was in place between model-derived and survey-derived elevation-volume curves, with 0.36% difference in volumes at full pool (Figure 10). The model grid includes Stanfield Marsh, which was not included in original WASP simulation, and allows simulation of supplemental water through the marsh to the main lake.

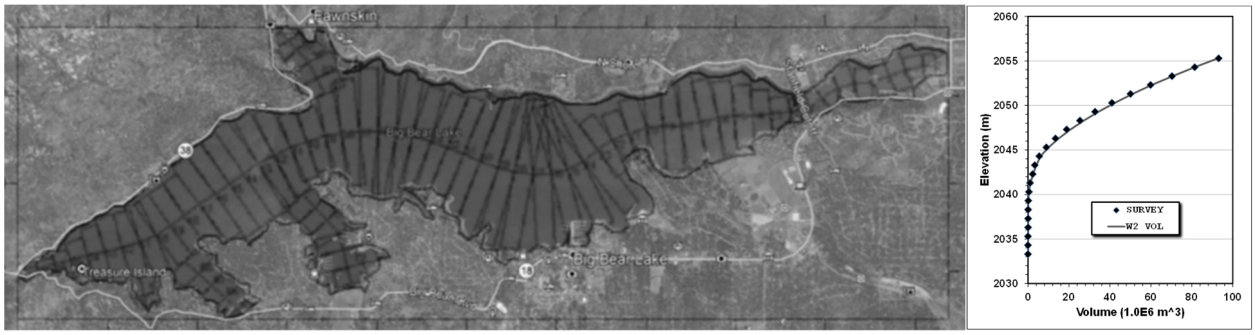

Figure 10. CE-QUAL-W2 model grid developed for Big Bear Lake. Inset depicts agreement between model and measured volume-elevation relationships.

Hydrologic data defining inflows, outflows, and withdrawals were developed from annual Water Master reports. The annual Water Master reports use measured outflows at the dam and water withdrawals by Bear Mountain Ski Resort, evaporative losses estimated using the Blaney Criddle equation, and measured lake surface elevations to derive monthly inflows to the lake. Hourly meteorological conditions were taken from Big Bear Airport and CIMIS Station #199 located at the golf course. Data included solar shortwave radiation (W/m^2), air temperature (°C), dewpoint temperature (°C), windspeed (m/s), wind direction (°) and cloud cover (%). Cloud cover was determined from sky cover conditions reported in METAR data for the airport. The model was calibrated against measured lake level, *in situ* profiles of temperature and dissolved oxygen (DO), and laboratory analyses of water samples collected at the lake.

1. Initial calibration and simulations of lake level, temperature and TDS

The initial model calibration efforts focused on reproducing observed lake levels (water balance) and water column temperatures (heat budget). Surface heat exchange was calculated term-by-term (shortwave, longwave, evaporative, and convective heat flux) with ice cover algorithm and fetch correction active. Vertical eddy viscosity was determined using the turbulent kinetic energy (TKE) formulation, with the Chezy bottom friction solution. Default heat exchange and hydraulic coefficients were generally used in simulations and are summarized in Appendix A.

Evaporation plays a dominant role in both water budget and heat budget calculations. As noted above, the Watermaster uses the Blaney Criddle equation, which is a very simple relationship that uses monthly average temperature and mean daily fraction of annual daylight hours (based on site latitude), to estimate monthly average reference evapotranspiration rate (ET_0) and evaporation rate. In contrast, CE-QUAL-W2 uses local windspeed and the vapor pressure gradient between water surface (based on water surface temperature) and overlying atmosphere (based on air temperature-relative humidity-dewpoint temperature) to determine evaporative heat and water flux on a sub-hourly basis, similar to approaches described in Chapra (2008) and Martin and McCutcheon (1999). The Blaney Criddle equation has been replaced in most applications by more sophisticated models, such as that described above for evaporation from free water surface, or the Penman-Montieth equation for reference ET_0 for estimated water demand for crops. One consequence of the use of a more accurate approach to calculating evaporation from the Lake is that inflows, which were calculated as residuals of water balance equation based upon monthly evaporation from Blaney Criddle equation, were not consistent with the improved evaporative flux rates in CE-QUAL-W2, resulting in over-estimates of water level (not shown). Thus, consistent with the Water Master approach, inflows were calculated from water balance with known lake levels, volumes and losses (with improved evaporative losses) using the CE-QUAL-W2 water balance utility. Also, as noted, the Blaney Criddle equation calculates monthly average evaporative loss, so the Water Master reports present monthly average inflows. Since weekly water surface elevation data was available, the water balance utility was able to provide finer resolution to the computed inflow data (Figure 11a). Outflow and seasonal withdrawals by the ski resort were used as reported in the Water Master Reports (Figure 11b). The severe storms and runoff generated in early 2011 represented the only substantial outflows from the lake beyond the in-stream flow requirements for Bear Creek downstream of the dam (Figure 11b). For initial water balance and TDS simulations, the distributed tributary approach was used. Allocations for specific creek discharges were used in water quality simulations and are described in more detail below.

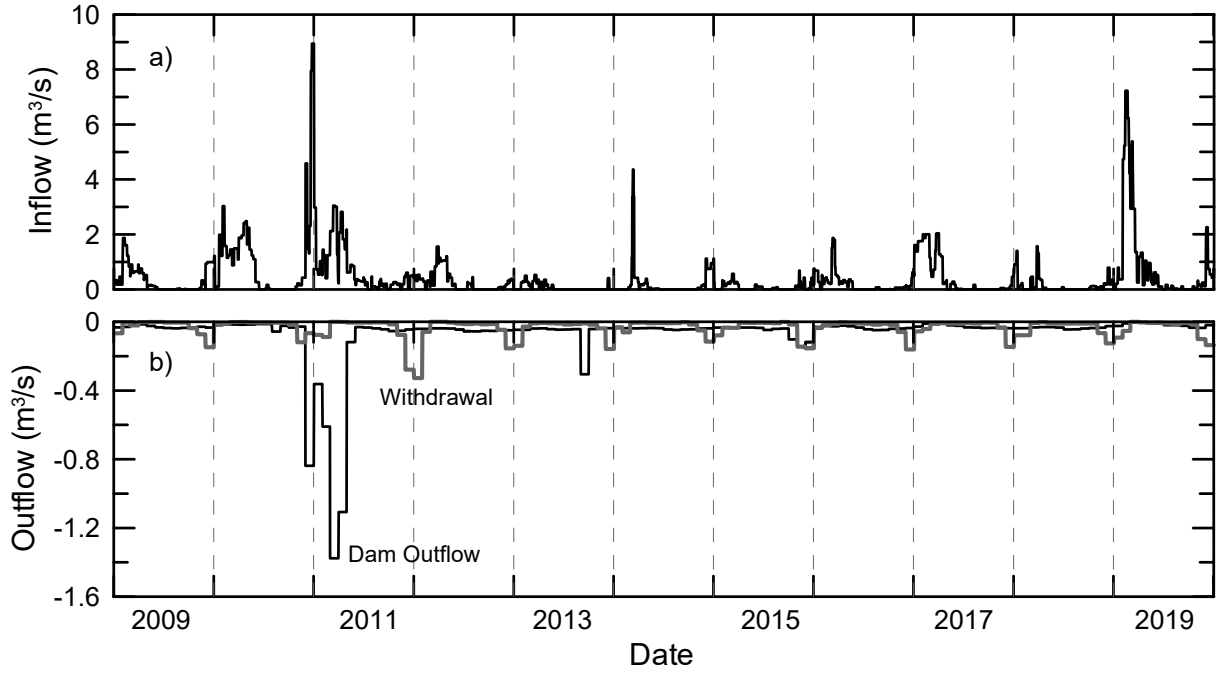

Figure 11. Hydrologic temporal boundary conditions for model calibration (2009-2019): a) total inflow and b) outflows due to withdrawals and dam outflow (from Water Master reports).

The outcome of the water balance calculations was an accurate prediction of lake level over the 2009-2019 calibration period (Figure 12). With the fitting of inflows, mean absolute error (MAE) between predicted and observed lake surface elevation was 3.6 cm.

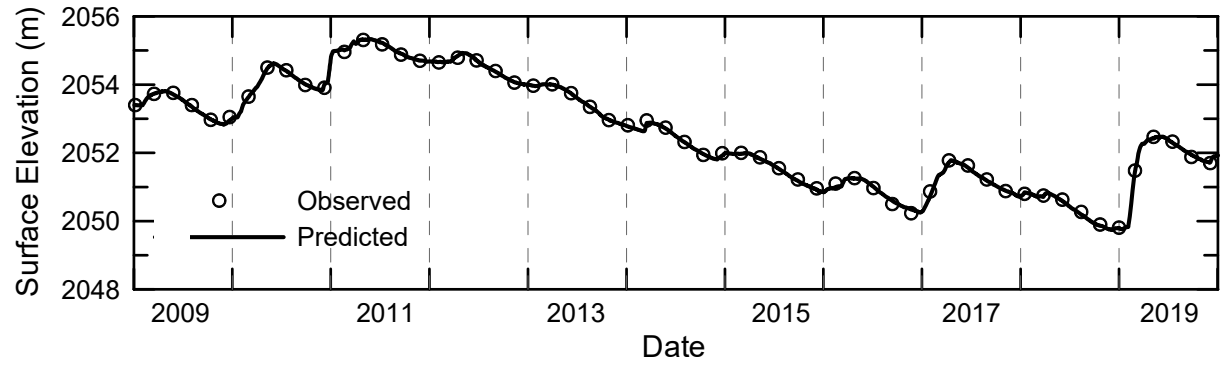

Figure 12. Predicted and observed water surface elevations.

Agreement between predicted and observed water levels is only partial confirmation of the suitability of the model for predicting water balance, since heat flux associated with evaporation is also a key component of the heat budget of lakes (Martin and McCutcheon, 1999). That is, water budgets and heat budgets are explicitly linked through the specific heat of vaporization of water. This is especially important for Big Bear Lake, where evaporation represents the principal mechanism for water loss from the lake (Santa Ana Water Board, 2005). The model quite

accurately reproduced temperature profiles in the lake (Figure 13). (Additional profile calibration figures are provided in Appendix B.)

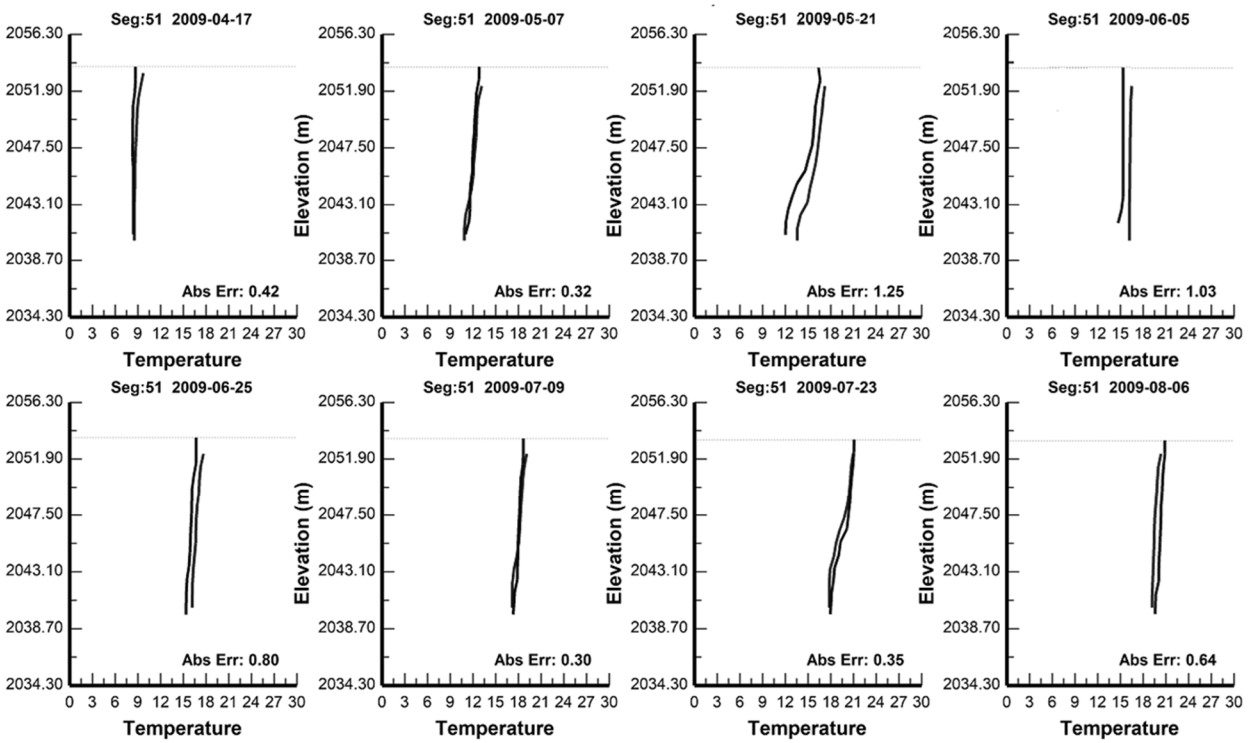

Figure 13. Model predicted and observed water column temperature profiles at station #1 (April 17 – August 6, 2009).

Mean absolute error (MAE) for temperature for profiles collected at the four TMDL sampling stations ranged from 0.95 – 1.14 °C (145 profiles, with 858-1974 discrete temperature measurements depending upon station) (Table 8).

Table 8. Mean absolute error for model predictions of water column temperatures at the four TMDL sampling stations (145 profiles; 858-1974 discrete measurements in each profile).

	#1 (Dam)	#2 (Gilner Pt)	#6 (Mid-lake)	#9 (Stanfield)
MAE (°C)	1.14	0.99	0.95	1.02

TDS concentrations were also simulated in the preliminary phase of model development and calibration. TDS concentration (g/L) was calculated from *in situ* specific conductance (mS/cm) in profile measurements with a proportionality constant of 0.65. Information about TDS (conductivity) of inflowing water was available only for very limited points in time, generally under low-moderate flow conditions. It was thus not feasible to develop comprehensive discharge-TDS relationships from available data. As an alternative, a general form of the discharge-TDS relation (inverse power law) developed from USGS gage #10260500 at Deep Creek was fitted to the Big Bear watershed of the form:

$$TDS\ (mg/L) = 36 * Q\ (m^3/s)^{-0.26} \qquad (1)$$

where Q represents the total flow to the lake derived from water budget calculations described previously. The relationship yielded a MAE of 13.3 mg/L (relative error of 15.4%) when applied to Metcalf and Summit Creek data.

Application of the TDS-flow equation to lake inflows, and simulation with CE-QUAL-W2 captured main features and trends in measured lake TDS (from conductivity) for 2009-19 (Figure 14). The MAE between predicted and observed lake TDS concentrations was 11.9 mg/L (4.8% relative error).

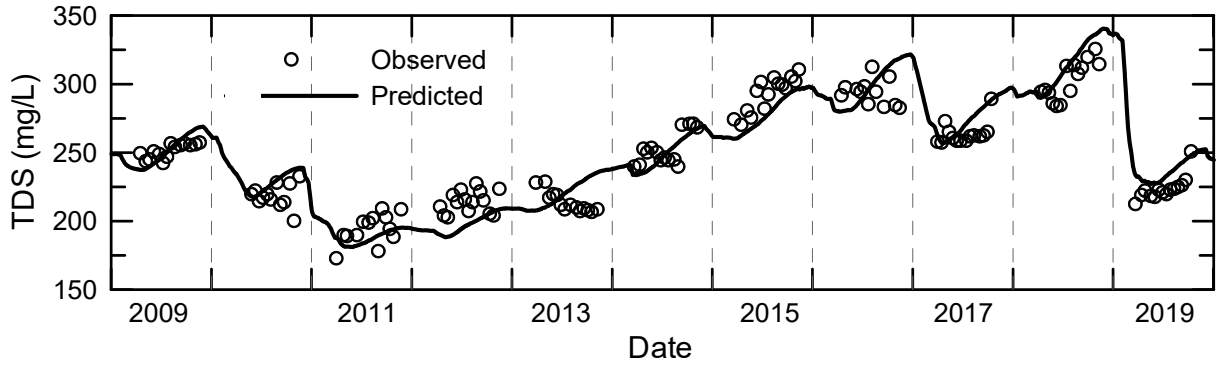

Figure 14. Predicted and observed TDS concentrations.

With the model reasonably representing lake level, water column temperature and TDS concentrations over the wide range of conditions present during 2009-2019, attention was then turned to water quality, focusing on nutrient and chlorophyll-a concentrations.

2. Calibration to Water Quality Data for Big Bear Lake

Lakes are recognized as complex ecosystems influenced by complicated physical, chemical, and biological properties, processes, and inter-relationships. Through the well-designed and high quality lake monitoring program conducted in support of the TMDL at Big Bear Lake, an excellent record of water column conditions and water quality is available with which to calibrate the CE-QUAL-W2 model. Watershed sampling has also been incorporated into the monitoring program, thus providing more extensive empirical information about nutrient and sediment contributions to the lake that were not available in earlier work, which chiefly relied on HSPF simulations of watershed runoff and loading to the lake.

As thoroughly described in the TMDL staff report, loading of nutrients to Big Bear Lake is from (i) external loading from point and nonpoint sources within the watershed, (ii) atmospheric deposition, (ii) internal recycling from bottom sediments, and (iv) macrophyte growth, senescence and death (Santa Ana Water Board, 2005). These processes were integral to the development and application of the CE-QUAL-W2 model for the lake, and are discussed in some detail below.

(i) External loading from the watershed

External loading (EL) (kg/d) from the watershed is the product of inflow rate Q_i (m^3/d) and influent concentrations C_i (kg/m^3) for each source i:

$$EL = \sum_{i=1}^{n} Q_i \, C_i \qquad (2)$$

Runoff rates from specific source areas were derived in previous modeling from HSPF simulations (Figure 15) and linked to WASP model segmentation, which excluded Stanfield Marsh (Figure 16) (Tetra Tech, 2004).

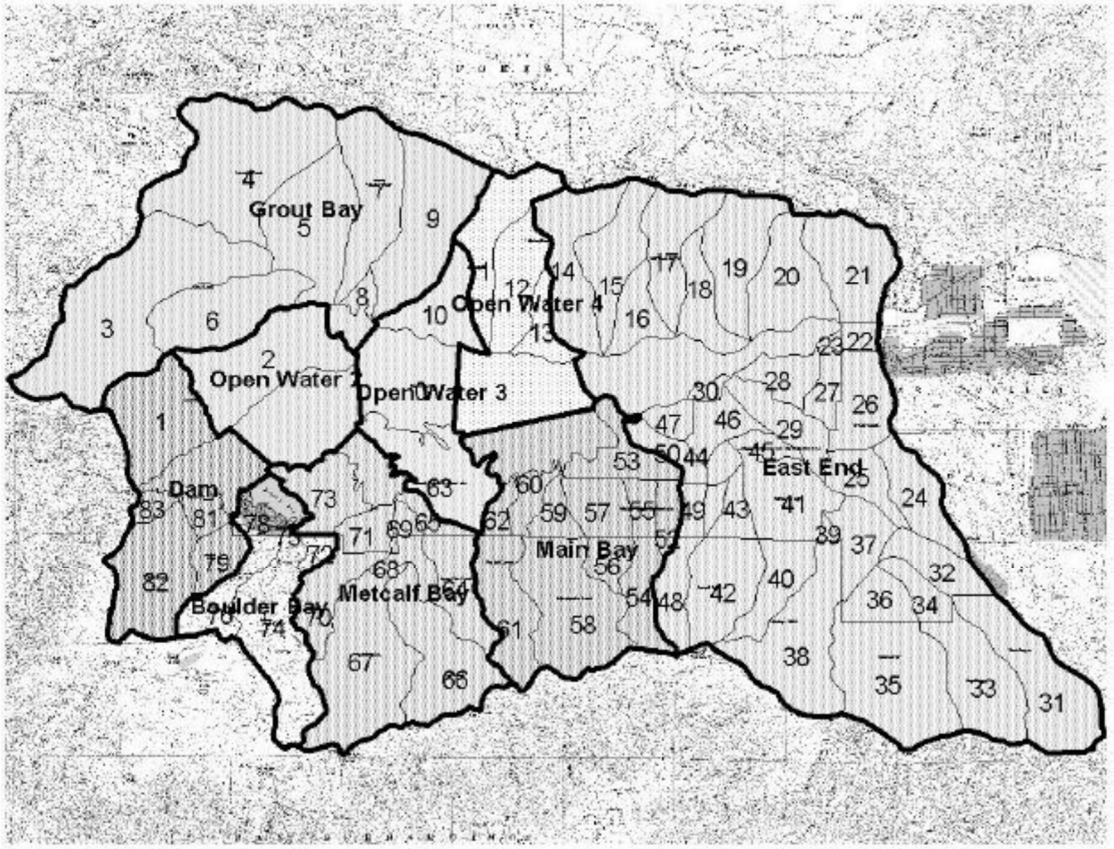

Figure 15. Contributing watershed areas to WASP segments developed from HSPF watershed model (Tetra Tech, 2004).

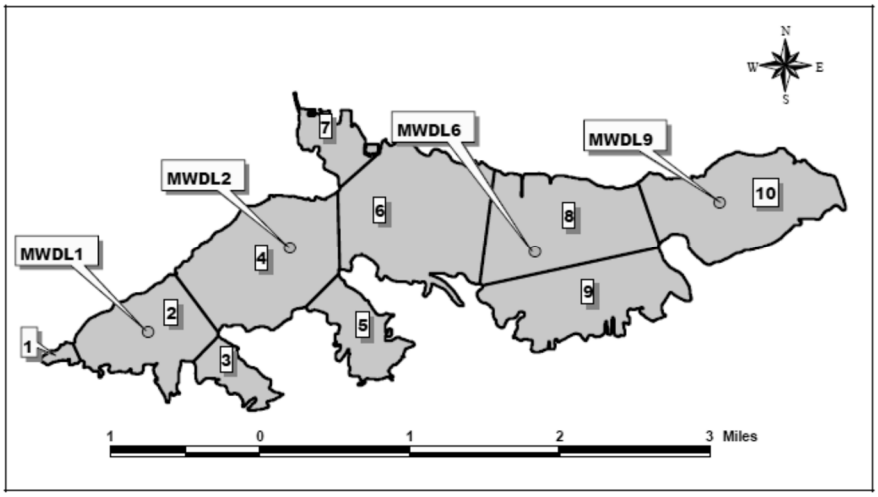

Figure 16. Model segmentation in previous WASP model simulations (Tetra Tech, 2004).

Total inflows, derived from water balance calculations described above, were allocated to regions of the lake following the approach used in the original WASP model. Total inflows (Figure 11a) were allocated to Boulder Bay, Metcalf Bay, Grout Bay and Rathbun Creek (Figure 17), based upon median % flows from prior HSPF simulation results. One difference with the earlier HSPF-WASP model approach is that the WASP model included flows to WASP segment 9 (Figure 16) as a distinct input; the coarse level segmentation in WASP does not map onto the 2-D laterally averaged grid of the CE-QUAL-W2 model, so distributed flow was used to represent both flows to segment 9 and from additional non-point sources (e.g., WASP segments 8 and 4 on the north side of the lake) (Figure 17). Distributed and Rathbun Creek flows in the CE-QUAL-W2 model collectively comprised over 65% of the total inflows to the lake.

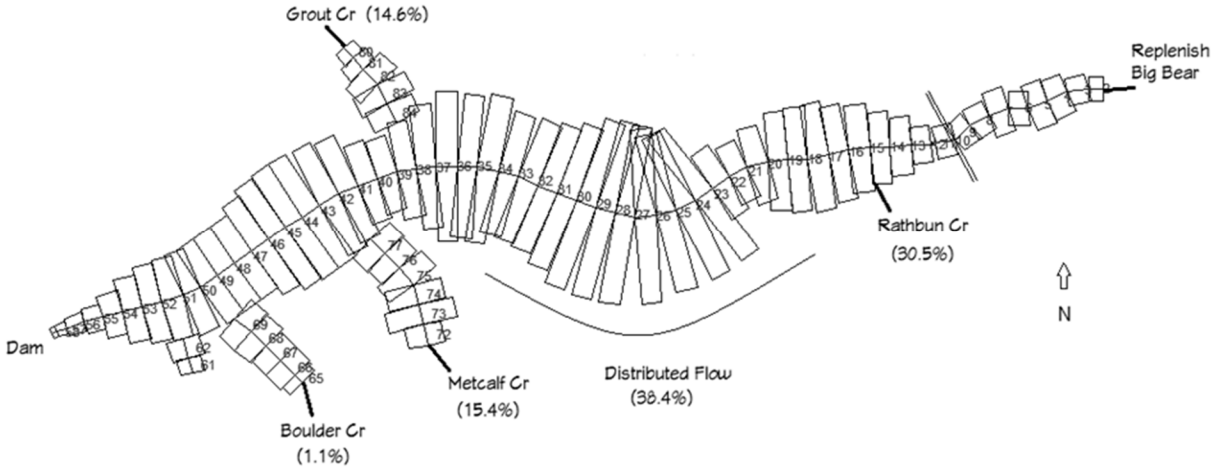

Figure 17. CE-QUAL-W2 model segmentation showing branch, tributary and distributed inflows.

Concentrations of nutrients within these different inflows over time were determined from available watershed monitoring data, rather than HSPF simulations as done in the initial WASP

model (More recent HSPF simulations have apparently been conducted, but results were unavailable.) Median concentrations based upon available data are provided in Table 9, while concentration ranges are presented in Table 10. A very limited set of measurements were identified for Boulder Creek and Grout Creek based on sampling in 2010-2011 (n=7 and 12, respectively). More extensive sampling was conducted for Knickerbocker, Rathbun, and Summit Creeks over 2010-2011 and 2016-2019 (n=53, 28 and 27, respectively). Although complete laboratory analyses on all samples were not always available. For example, laboratory measurements of total Kjeldahl N (TKN), dissolved Kjeldahl N (DKN), total organic carbon (TOC) and dissolved organic carbon (DOC) were only available for samples collected since 2016.

Table 9. Median concentrations (mg/L) of nutrients and organic C in creek water samples.

Creek	**TP**	**o-P**	**TN**	**TKN**	**DKN**	**NH_4-N**	**NO_3-N**	**TOC**	**DOC**
Boulder (n=7)	0.009	0.007	0.184	-	-	0.011	0.022	-	-
Grout (n=12)	0.024	0.015	0.282	-	-	0.008	0.121	-	-
Knickerbocker(n=53)	0.055	0.038	0.374	0.34	0.22	0.130	0.130	2.9	2.7
Rathbun (n=28)	0.055	0.038	0.786	0.46	0.36	0.419	0.419	5.1	4.9
Summit (n=27	0.069	0.021	0.530	0.52	0.25	0.180	0.180	6.0	3.6

Concentrations of total and dissolved forms of N and P varied widely, often by an order of magnitude or more, within the sampling conducted at the creeks (Table 8).

Table 10. Range in concentrations (mg/L) of nutrients and organic C in creek water samples.

Creek	**TP**	**o-PO_4-P**	**TN**	**NH_4-N**	**NO_3-N**
Boulder	0.005 - 0.017	0.005 - 0.009	0.130 - 1.103	0.007 - 0.040	0.002 - 0.042
Grout	0.010 - 0.037	0.010 - 0.026	0.083 - 1.263	0.005 - 0.057	0.011 - 1.054
Knickerbocker	0.020 - 0.320	0.010 - 0.160	0.142 - 1.770	0.005 - 0.290	0.021 - 1.200
Rathbun	0.020 - 0.180	0.010 - 0.100	0.270 - 1.890	0.008 - 0.300	0.005 - 1.190
Summit	0.020 - 0.378	0.003 - 0.155	0.023 - 1.300	0.007 - 0.220	0.003 - 0.602

Table 10 (contd). TOC and DOC values not reported for Boulder or Grout Creek.

Creek	**TKN**	**DKN**	**TOC**	**DOC**
Knickerbocker	0.12 - 1.20	0.012 - 0.67	1.3 - 12.0	1.4 - 8.8
Rathbun	0.077 - 1.40	0.21 - 0.77	2.9 - 7.7	2.6 - 7.1
Summit	0.10 - 0.95	0.00 - 0.78	2.8 - 7.5	2.2 - 7.0

Water quality in runoff can vary strongly depending upon characteristics of the basin, including land use, land cover, amount of impervious surfaces and other factors, and are reflected in the higher concentrations of nutrients in Knickerbocker, Rathbun, and Summit Creeks compared with Boulder and Grout Creeks (Tables 9, 10). The nature and intensity of storms (rain, snow, rain-on-snow), meteorological, and antecedent watershed conditions influence discharge and also influence water quality, contributing to the wide range in concentrations observed at the creeks (Table 10). Since a very limited number of point estimates of flow were available, it was not feasible to develop reach-specific discharge-water quality relationships, but total flows to the lake were known from water balance considerations. Measured nutrient concentration were statistically evaluated for possible correlations with total flow rates (Table 11). Sample sizes varied by creek, with only 7 and 12 samples collected from Boulder Creek and Grout Creek, respectively, while Knickerbocker, Rathbun, and Summit Creeks were sampled 53, 28 and 27

times, respectively. Weak correlations with total flow were observed for most variables, although total flow accounted for a meaningful fraction of the total variance in NO_3-N concentrations (up to R-value of 0.62, or R^2 of 0.38, representing 38% of observed variance in NO_3-N concentration for Rathbun Creek). Nonetheless, regressions even for NO_3-N had modest predictive power (Table 11, Figure 18). Assumptions about inflows and influent concentrations were necessitated by the limited amount of data and thus represent a significant source of uncertainty in model predictions.

Table 11. Correlation coefficients between flow and constituent concentrations.

Creek	**TP**	**o-P**	**TN**	**TKN**	**DKN**	**NH_4-N**	**NO_3-N**	**TOC**	**DOC**
Boulder	0.41	0.31	-0.13	-	-	0.29	-	-	-
Grout	0.52	0.61	0.52	-	-	0.42	0.48	-	-
Knickerbocker	0.00	0.06	-0.03	0.01	0.00	-0.14	0.19	0.13	0.34
Rathbun	-0.21	-0.20	0.28	0.04	0.38	-0.12	0.62	0.43	0.53
Summit	-0.05	0.04	0.08	0.21	0.66	-0.02	0.52	0.18	0.38

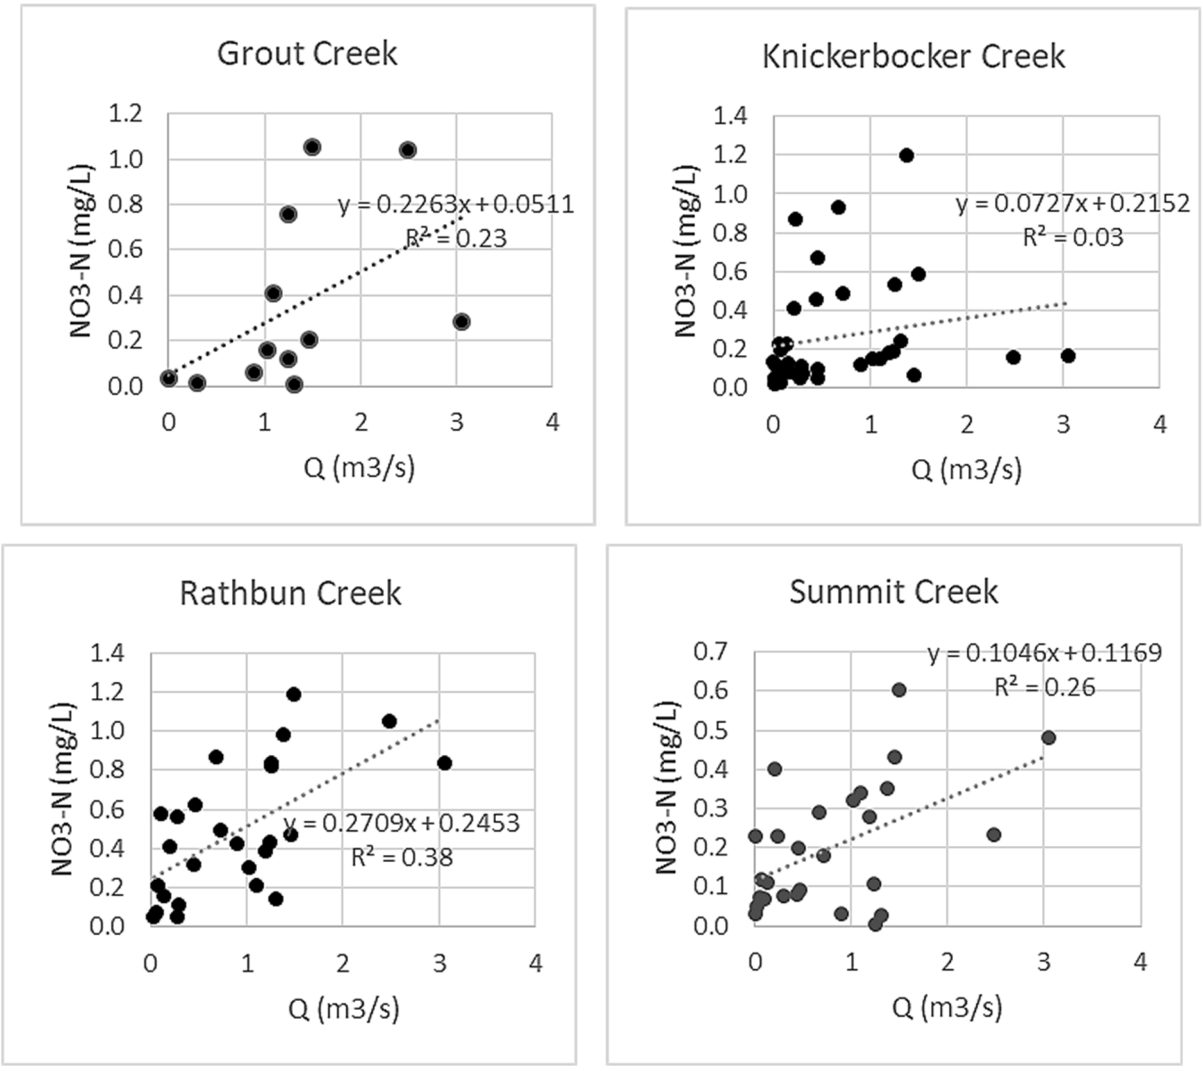

Figure 18. Plots and regression lines between NO3-N concentrations and total (lakewide) flow for a) Grout Creek, b) Knickerbocker Creek, c) Rathbun Creek, and d) Summit Creek.

Measured nitrogen and phosphorus concentrations were used when available and assumed to represent influent concentrations for the entire month in which the measurements were made; for time periods when measured values were not available, median values were used, except as follows: NO_3-N (all creeks except Boulder) and PO_4-P (Grout and Knickerbocker only), when concentrations were estimated from regressions with total flow for that date. The incorporation of measured, median, and regression-based influent concentrations into model input time-series is illustrated for Rathbun Creek (Figure 19).

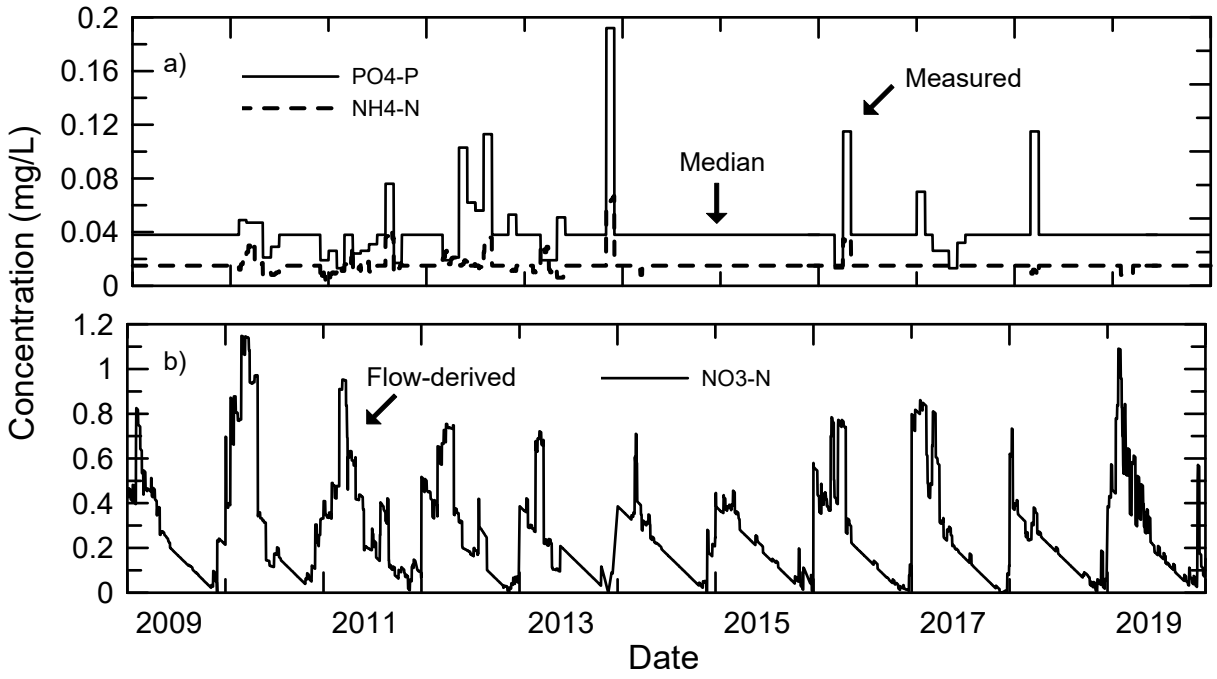

Figure 19. Modeled input nutrient concentrations in Rathbun Creek: a) PO4-P and NH4-N illustrating use of measured values when available and median values when not, and b) NO3-N concentrations derived from regression with total flow rate.

Particulate forms of N, P, and C were calculated by difference between total and dissolved forms. Following White et al. (2010) and Wetzel (1984), organic matter was further partitioned into labile and refractory forms (approximately 25 and 75%, respectively).

(ii) Atmospheric deposition

In addition to external loading from the watershed, atmospheric deposition is also an important source of N and P to Big Bear Lake. Based upon available studies by Mark Fenn and others in the San Bernardino Mountains, direct deposition of N onto the lake (assumed for modeling purposes to be equimolar NH_4 and NO_3) was estimated to be approximately 10 kg/ha/yr, while direct deposition of total P was assumed to be $1/20^{th}$ that of N, or 0.5 kg/ha/yr (Santa Ana Water Board, 2005). The CE-QUAL-W2 model does not simulate transformations and release of P bound to inorganic particles, so it was assumed that 40% of the total P (chiefly as fine inorganic dust particles) was in a bioavailable form and deposited as PO_4-P.

(iii) Internal recycling from bottom sediments

Release from bottom sediments through mineralization of organic matter and reductive dissolution of ferric oxyhydroxides was simulated in CE-QUAL-W2 using the dynamic 1^{st}-order sediment decay model combined with the 0-order SOD model. The 1^{st}-order sediment model uses a sediment compartment to accumulate organic sediments as a result of settling of algae and particulate organic matter, and allow their decay, releasing NH_4-N and PO_4-P back to the water column (Figure 20).

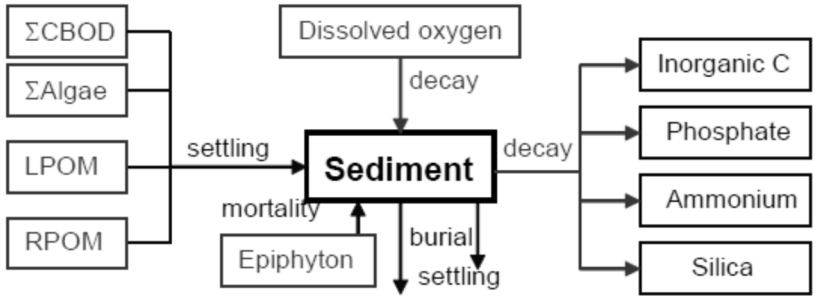

Figure 20. Schematic of 1st-order sediment subroutine in CE-QUAL-W2.

As a 1st-order process, the greater the amount of organic matter settling to the sediment compartment results in greater amounts of organic matter decayed, and N and P mineralized and released back to water column (i.e., recycled). Simulation values are provided in Table 12.

Table 12. 1st-order sediment model parameter values used in simulations. Default W2 values from Wells (2019).

Parameter	Default	Value	Description
SEDCI	0	4.4	Initial reactive sediment concentration (g/m^3)
SEDS	0.1	0.08	Sediment settling rate (m/d)
SEDK	0.1	0.1	Sediment decay rate (d^{-1})
FSOD	1	0.23	Fraction of 0-order SOD rate used
FSED	1	1	Fraction of 1st-order sediment concentration used
SEDBR	0.01	0.01	Sediment burial rate (d^{-1})

The 1st-order model simulates aerobic decomposition reactions, so sediment oxygen demand is also dynamically calculated based upon amount and type of organic matter and temperature, and depletion of DO in turn reduces rates of organic matter mineralization and deamination-dephosphorylation reactions. The 1st-order sediment model thus doesn't simulate nutrient release under anaerobic conditions, although, anaerobic decomposition and reductive dissolution reactions can be important processes within nutrient cycling. As a result, the 0-order SOD model (Figure 21) was used to simulate N and P nutrient release during anaerobic conditions. Maximum values for SOD were varied from 0.1 for shallow low organic matter sediments to 1.0 $g/m^2/d$ at TMDL station #1 and 1.2 $g/m^2/d$ for deepest high organic sediments adjacent to the dam; rates were assumed to vary linearly with temperature between 4 and 30°C, corresponding to a maximum summer 0-order SOD rate of about 0.6 $g/m^2/d$ at TMDL station #1.

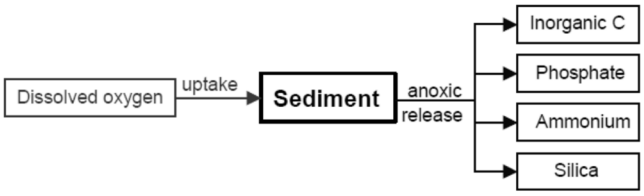

Figure 21. Schematic of 0th-order sediment oxygen demand subroutine in CE-QUAL-W2.

(iv) Macrophyte growth, senescence, and death

Macrophytes are an important component of Big Bear Lake's ecosystem, providing habitat for fish, zooplankton, larval aquatic insects, a variety of benthic animals, and epiphytic periphyton. Aquatic vegetation surveys have periodically been conducted, with coontail, common waterweed, and Eurasian watermilfoil often comprising much of the total macrophyte biomass. Macrophyte growth, senescence, and death are also important features of the nutrient cycle of the lake. Harvesting and herbicide applications have helped control macrophyte growth, with harvesting also serving as strategy to export nutrients from the lake. CE-QUAL-W2 includes macrophyte subroutines that simulate plant life cycles and their effect on hydrodynamics, nutrients, light, and other factors.

Since detailed information about the species composition, density, and distribution of macrophytes over the 2009-2019 timeframe was not available, a composite macrophyte group was incorporated into the model. CE-QUAL-W2 modeling conducted by the USGS (2013) for the Klamath River upstream of Keno Dam, Oregon served as the basis for macrophyte submodel parameterization (Table 13). The composite macrophyte extracted nutrients from the water column, as coontail and to a slightly lesser extent milfoil do, and from bottom sediments, as typical rooted aquatic vascular plants do.

Table 13. Macrophyte model parameter values used in simulations.

Parameter	USGS[a]	Value	Description
MG	0.34	0.3	Maximum macrophyte growth rate (d^{-1})
MR	0.09	0.09	Maximum macrophyte respiration rate (d^{-1})
MM	0.06	0.06	Maximum macrophyte mortality rate (d^{-1})
MSAT	5	10	Light saturation intensity at max photosynthesis rate (W/m^2)
MPOM	0.7	0.7	Fraction of macrophyte biomass converted to POM upon death
LRPMAC	0.2	0.2	Fraction of POM that becomes labile POM
PSED	0.4	0.27	Fraction of P uptake from sediments
NSED	0.4	0.27	Fraction of N uptake from sediments
MBMP	40	40	Threshold concentration when growth to next layer (g/m^3)
MMAX	108	1000	Maximum macrophyte concentration (g/m^3) (W2 default = 500 g/m^3)
CDDRAG	0	1	Macrophyte drag coefficient
MT1	14	14	Lower temperature for rising growth rate function (°C)
MT2	24	24	Upper temperature for rising growth rate function (°C)
MP	0.004	0.005	Stoichiometric ratio between P and biomass (g/g)
MN	0.054	0.05	Stoichiometric ratio between N and biomass (g/g)
MC	0.51	0.5	Stoichiometric ratio between C and biomass (g/g)

[a]composite macrophyte based on average of values for Coontail and Common Waterweed. USGS (2013).

v. Epiphyton dynamics

A vast majority of algal species can colonize surfaces, including macrophytes, and can approach or exceed primary production of macrophytes (*e.g.,* Jones, 1984). Given the relatively shallow depths in the embayments and eastern end of the lake and relatively high water clarity much of the year, epiphyton were also included in the model. Epiphyton are subject to the same

environmental factors and processes as phytoplankton with the exception of settling loss from the water column (Table 14).

Table 14. Epiphyton model parameter values used in simulations. Default W2 values from Wells (2019).			
Parameter	Default	Value	Description
EG	2	2	Maximum epiphyton growth rate (d^{-1})
ER	0.04	0.045	Maximum epiphyton respiration rate (d^{-1})
EE	0.04	0.045	Maximum epiphyton excretion rate (d^{-1})
EM	0.1	0.1	Maximum epiphyton mortality rate (d^{-1})
EB	0.001	0.001	Epiphyton burial rate (d^{-1})
EHSP	0.003	0.003	Epiphyton half-saturation for P-limited growth (g/m^3)
EHSN	0.014	0.014	Epiphyton half-saturation for N-limited growth (g/m^3)
EHSSI	0	0	Epiphyton half-saturation for Si-limited growth (g/m^3)
ESAT	75	75	Light saturation intensity at max photosynthesis rate (W/m^2)
EHS	35	82	Biomass limitation factor (g/m^2)
ENEQN	2	2	Ammonia preference factor equation (1 or 2)
ENPR	0.001	0.001	N-half saturation preference constant (g/m^3)
EP	0.005	0.003	Stoichiometric ratio between P and biomass (g/g)
EN	0.08	0.082	Stoichiometric ratio between N and biomass (g/g)
EC	0.45	0.45	Stoichiometric ratio between C and biomass (g/g)

vi. Phytoplankton dynamics

With information about external nutrient loading from the watershed, atmospheric deposition, internal nutrient recycling, and role of macrophytes and epiphyton, attention was then turned to parameterization of the model to reproduce seasonal and interannual phytoplankton dynamics as expressed through trends in chlorophyll-a. Algal levels are governed by the availability of nutrients and light, and regulated by a complex set of processes, including respiration, settling, grazing, and mortality (Figure 22):

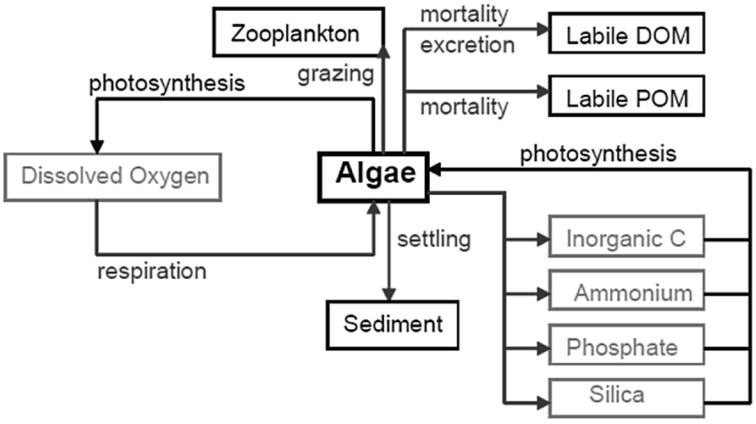

Figure 22. Schematic of phytoplankton subroutine in CE-QUAL-W2.

No specific genus or species was simulated and parameter values at or near CE-QUAL-W2 default values were used (Table 15). Two phytoplankton groups were simulated, with algal group #2 capable of N_2-fixation.

Table 15. Phytoplankton model parameter values used in simulations. Default W2 values from Wells (2019).

Parameter	Default	Algae 1	Algae 2	Description
AG	2	2	1.7	Maximum algal growth rate (d^{-1})
AR	0.04	0.04	0.05	Maximum algal respiration rate (d^{-1})
AE	0.04	0.04	0.05	Maximum algal excretion rate (d^{-1})
AM	0.1	0.1	0.1	Maximum algal mortality rate (d^{-1})
AS	0.1	0.1	0.1	Algal settling rate (d^{-1})
AHSP	0.003	0.003	0.005	Algal half-saturation for P-limited growth (g/m^3)
AHSN	0.014	0.03	0	Algal half-saturation for N-limited growth (g/m^3)
AHSSI	0	0	0	Algal half-saturation for Si-limited growth (g/m^3)
ASAT	100	90	100	Light saturation intensity at max photosynthesis (W/m^2)
ALPOM	0.8	0.8	0.8	Fraction of algae lost by mortality to POM
ANEQN	2	1	1	Ammonia preference factor equation (1 or 2)
ANPR	0.001	0.001	0.001	N-half saturation preference constant (g/m^3)
AP	0.005	0.003	0.0031	Stoichiometric ratio between P and biomass (g/g)
AN	0.08	0.09	0.09	Stoichiometric ratio between N and biomass (g/g)
AEC	0.45	0.45	0.45	Stoichiometric ratio between C and biomass (g/g)

3. Model Calibration Results

As previously noted, water quality in Big Bear Lake varied widely over 2009-2019 (Table 1). The model reproduced seasonal and inter-annual variations in chlorophyll-a concentrations reasonably well, including increased concentrations in the latter half of the 2009-2019 study period associated with lower lake levels (Figure 23).

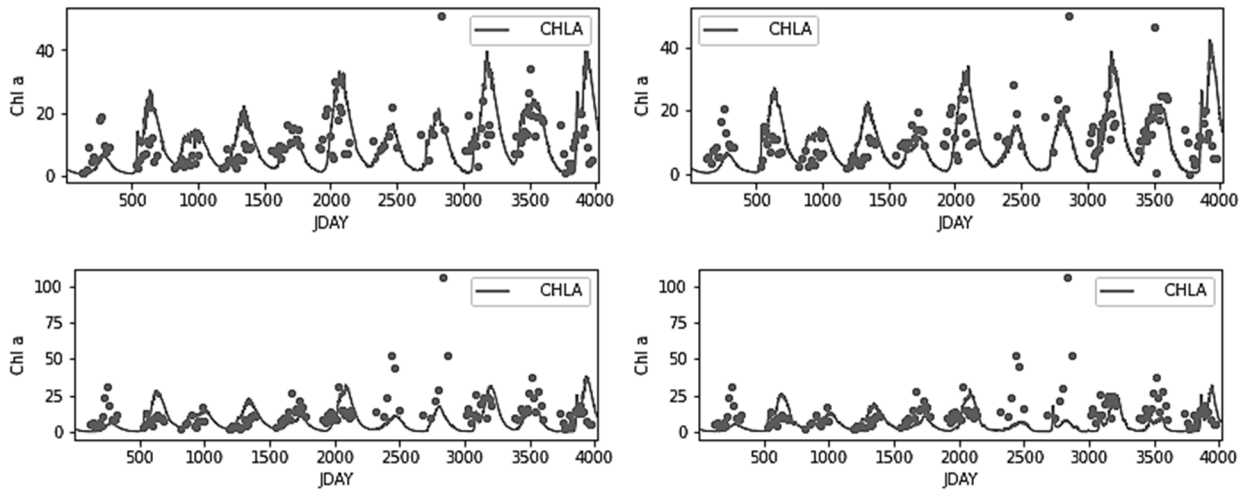

Figure 23. Predicted (line) and observed (circles) chlorophyll-a concentrations (µg/L) over 2009-2019 calibration period for TMDL sampling stations: a) #1 (dam), b) #2 (Gilner Point), c) #6 (Mid-lake), and d) #9 (Stanfield). JDAY represents simulation day (elapsed Julian day) since 1/1/2009.

The model also reproduced central tendencies present in measured TP concentrations, including seasonal variations and trends of increased concentrations in the latter half of the 2009-2019 study period, but predicted seasonal variations that were dampened relative to reported data (Figure 24). In particular, the model over-predicted total P around day 2300-2600 which corresponds to the alum application in 2015. CE-QUAL-W2 doesn't have subroutines specifically simulating an alum application, and after some effort, it was deemed not readily feasible to accurately simulate the flocculation, sorption, and settling of alum and sorbed P and N within CE-QUAL-W2. Some limitations to the macrophyte submodel were also identified (Appendix C).

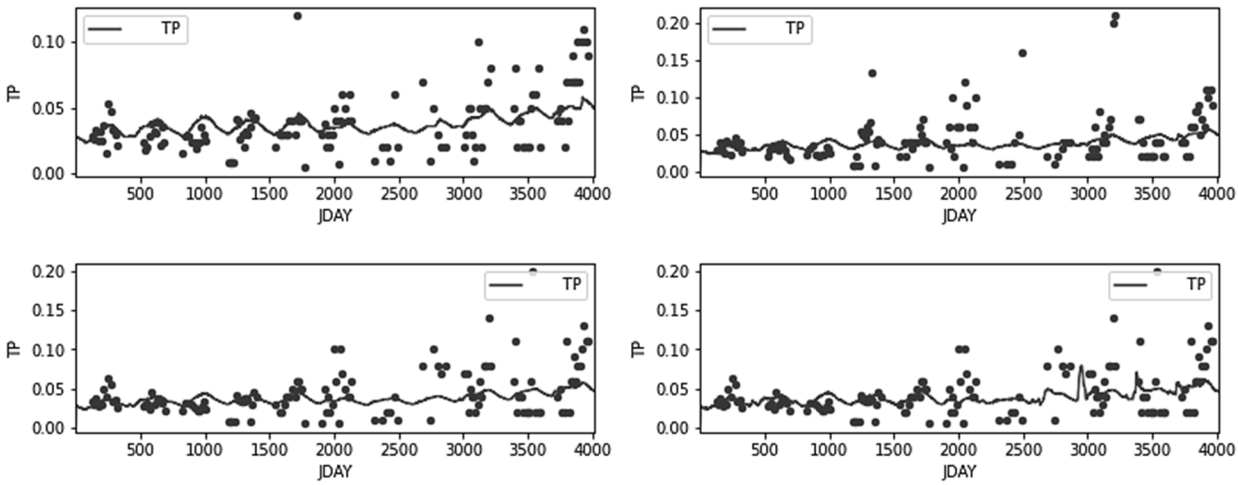

Figure 24. Predicted (line) and observed (circles) total P (TP) concentrations (mg/L) over 2009-2019 calibration period for TMDL sampling stations: a) #1 (dam), b) #2 (Gilner Point), c) #6 (Mid-lake) and d) #9 (Stanfield). JDAY represents simulation day (elapsed Julian day) since 1/1/2009.

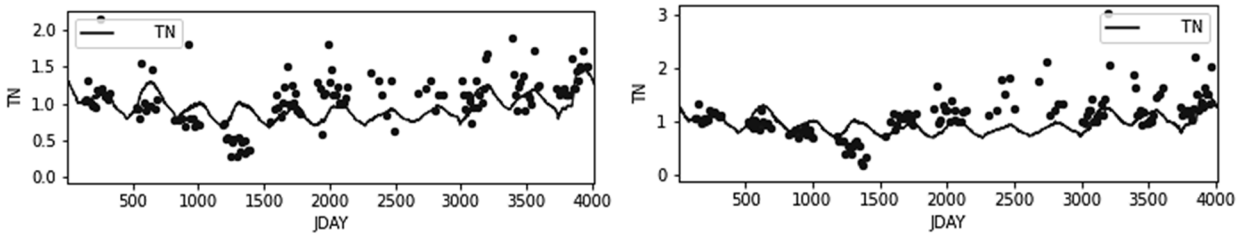
The predicted increase in algal biomass corresponding to the alum application in 2015 might be expected to increase N concentrations somewhat, as further P-limitation would restrict amount of N also incorporated into algal biomass.



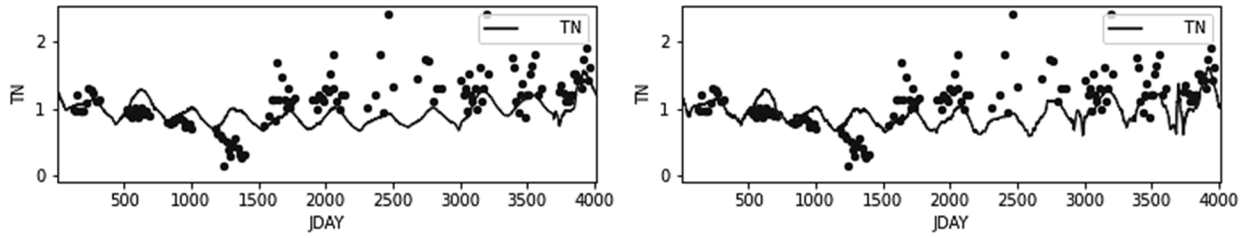


Figure 25. Predicted (line) and observed (circles) total N (TN) concentrations (mg/L) over 2009-2019 calibration period for TMDL sampling stations: a) #1 (dam), b) #2 (Gilner Point), c) #6 (Mid-lake) and d) #9 (Stanfield). JDAY represents simulation day (elapsed Julian day) since 1/1/2009.

As evident in Figures 23-25, very wide swings in reported total nutrient and chlorophyll-a concentrations were sometimes present, with sample concentrations occasionally up to 3-5 times higher than samples collected immediately prior to or immediately thereafter (e.g., Figure 24, TP concentration of 0.12 mg/L around day 1700 for TMDL station #1). While analytical error is present in all measured values, a Grubbs outlier test was used to identify outliers at $p<0.01$ prior to calculation of model error statistics. A total of 7/424 outliers were statistically identified for chlorophyll-a, 5/600 for total P, 2/600 for total N and 6/600 for total inorganic N. Outliers removed due to analytical, sample handling, or other errors thus constituted only 0.33-1.6% of total reported values. Even with removal of outliers at $p<0.01$, it nonetheless bears noting that model calibration errors have field and laboratory errors imbedded within them, as well as from other factors (Harmel et al., 2006). Model error statistics, including mean error, mean absolute error, and root mean square error, are summarized in Table 16.

Table 16. Model error results for nutrients and chlorophyll-a.

Property	N	Range	ME	MAE	RMSE	RRMSE (%)[a]
Chlorophyll-a (µg/L)	417	0.5 – 43.2	-1.3	7.9	10.3	24.0
Total P (mg/l)	595	0.005 - 0.180	-0.010	0.022	0.031	17.7
Total N (mg/L)	598	0.126 - 2.415	-0.148	0.310	0.413	18.0
Total Inorganic N (mg/L)	594	0.007 - 0.319	-0.049	0.050	0.092	29.5

[a]=(RMSE/Range)*100

Dissolved oxygen concentrations are influenced by, and also often regulate, the biogeochemical processes operating in the lake. It was previously shown that the model adequately reproduced water column temperatures (Figure 13, Table 8); the model was also generally successful in reproducing measured DO concentrations (*e.g.*, Figure 26, Table 17). (Additional profiles provided in Appendix D). While the lake was often relatively well-mixed vertically, low DO concentrations above the sediments were frequently present as a result of aerobic decomposition and respiration reactions.

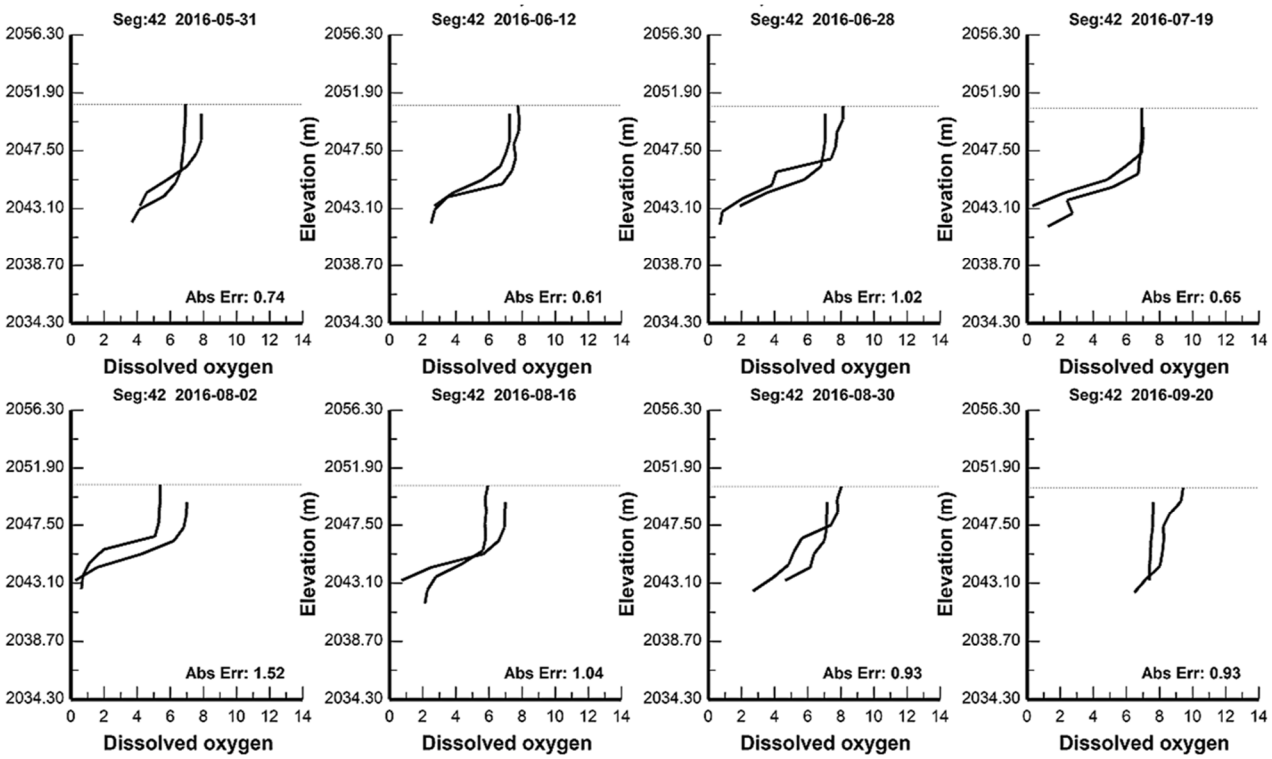

Figure 26. Example dissolved oxygen profiles at TMDL station #2 highlighting agreement between predicted and measured concentrations and periodic loss of DO in lower water column.

Table 17. Mean absolute error for model predictions of water column DO concentrations at the four TMDL sampling stations (145 profiles; 858-1974 discrete measurements in each profile).

	#1 (Dam)	#2 (Gilner Pt)	#6 (Mid-lake)	#9 (Stanfield)
MAE (mg/L)	1.40	1.25	1.16	1.02

Summary

A 2-D (longitudinal-vertical) hydrodynamic -water quality model for Big Bear Lake was developed using CE-QUAL-W2. The 2-D laterally-averaged model grid was developed from the bathymetric survey data collected by Fugro Pelagos Inc. (2006). Hydrologic data defining inflows, outflows, and withdrawals were developed from annual Big Bear Water Master reports. Hourly meteorological conditions were taken from Big Bear Airport and California Irrigation Management Information System (CIMIS) Station #199 located at the golf course. Data included solar shortwave radiation, air temperature, dewpoint temperature, windspeed, wind direction and cloud cover. Cloud cover was determined from sky cover conditions reported in METAR data for the airport. The model was calibrated against measured lake level, *in situ* profiles of temperature and DO, and laboratory analyses of water samples collected at the lake for 2009-2019. The model was first developed and calibrated for lake level, water column temperature profiles and TDS, where generally very good agreement was achieved (mean absolute errors of 3.6 cm, 0.79-0.89 °C, and 11.9 mg/L, respectively). Following this, model calibration to water quality data was conducted. The model included external nutrient loading from the watershed,

atmospheric deposition, internal nutrient recycling, and nutrient uptake and release associated with macrophyte and epiphyton growth, senescence and death. Two algal groups were simulated, included one representing cyanobacteria capable of N_2-fixation. The 1^{st}-order dynamic sediment model was combined with the 0^{th}-order SOD model to simulate nutrient recycling and DO uptake in the surficial bottom sediments. Relative root mean square error was 17.7% for total P, 18.0% for total N, 29.5% for TIN, and 24.0 % for chlorophyll-a. Mean absolute errors for DO ranged from 1.02 – 1.40 mg/L for the 4 TMDL sampling stations.

IV. APPLICATION OF MODEL TO EVALUATE CONDITIONS WITH REPLENISH BIG BEAR PROJECT

With some confidence that the model is able to reproduce trends in water quality over a wide range of conditions, the model was used to evaluate changes in lake level and water quality under selected Replenish Big Bear project treatment scenarios. For these simulations, 1,920 af of BBARWA WWTP effluent was delivered annually through Stanfield Marsh and subsequently to the Lake. Three progressive levels of treatment assuming advanced nutrient removal and reverse osmosis (RO) technologies were evaluated (Treatment Alternatives):

(i) Alternative 1: TIN & TP Removal
(ii) Alternative 2: 70% RO (70% RO + 30% TIN & TP Removal)
(iii) Alternative 3: 100% RO

The composition of the supplemental water used in simulations varied quite substantially depending upon level of treatment (Table 18).

Table 18. Water quality of supplemental water used in model simulations (WSC, 2020b).

Constituent (mg/L)	Alternative 1	Alternative 2	Alternative 3
TDS	450	150	50
NO_3-N	0.6	0.2	0.05
NH_4-N	0.2	0.1	0.05
PO_4-P	0.25	0.06	0.02
Dissolved Organic N	1.33	0.76	0.5
Dissolved Organic P	0.24	0.04	0.01
Particulate Organic N	0.07	0.04	0.00
Particulate Organic P	0.01	0.002	0.00

These three Treatment Alternatives, with varying concentrations of TDS, phosphorus, and nitrogen (Table 18), and a flow rate of 1,920 af/yr were simulated to evaluate effects of supplementation on lake levels and concentrations of TDS, nutrients and chlorophyll-a concentrations for comparisons with baseline (2009-2019) conditions. This analysis thus allows one to compare how different Replenish Big Bear Treatment Alternatives would have altered lake conditions over the past decade, which included extreme variations in lake level and water quality.

A. Lake Level

A simple water balance calculation indicates that 1,920 af/yr of water added to Big Bear Lake would add approximately 0.2 m/yr to lake level. This level of supplementation represents about a 20% increase in average total annual inflow on a calendar year basis, with substantially larger relative contributions during periods of drought (e.g., nearly doubling the very low inflow shown in Fig. 11a during 2013). Simulations confirm that supplemental water would have increased lake level substantially over the natural 2009-2019 period (Baseline scenario), up to 1.7 m by late 2018 relative to no project (Figure 27).

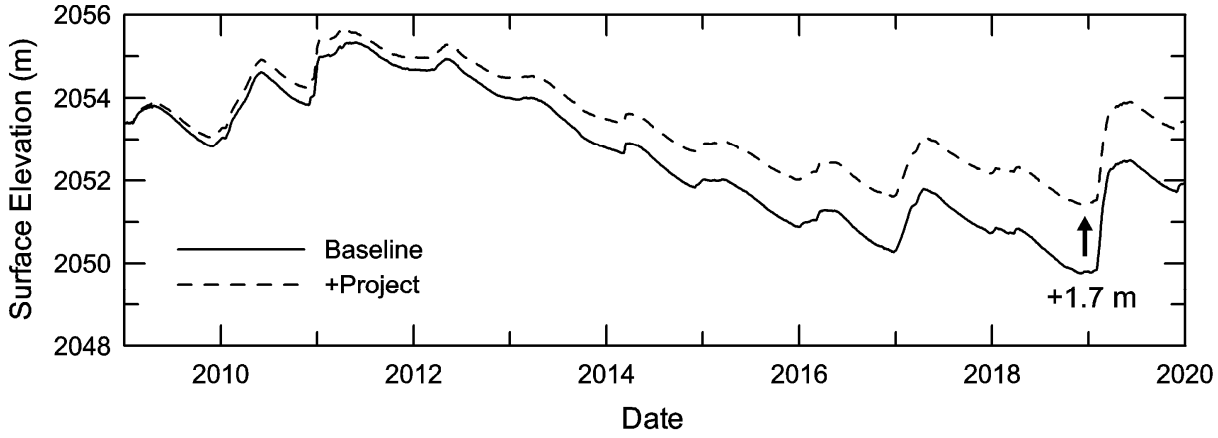

Figure 27. Predicted lake surface elevations over 2009-2019: baseline and with project.

B. Lake Area

The supplemental water also translates to increased lake surface area (Figure 28) that is a function of elevation-volume-area relationships for the Lake basin (Figure 9). Benefits of increased Lake area are especially evident during periods of drought, when Lake shoreline has substantially receded, limiting recreational and homeowner access, and resulting in extensive loss of the littoral community. For example, supplementation with project water would have increased lake area by about 300 acres, from less than 1,900 acres in 2018 to nearly 2,200 acres (Fig. 28). Moreover, the benefits of supplementation to Lake level and Lake surface area in terms of recreational access, aesthetics, ecological habitat, etc. accrue over time, especially evident during drought, until large inflows restore lake level and reset hydrologic conditions in the Lake.

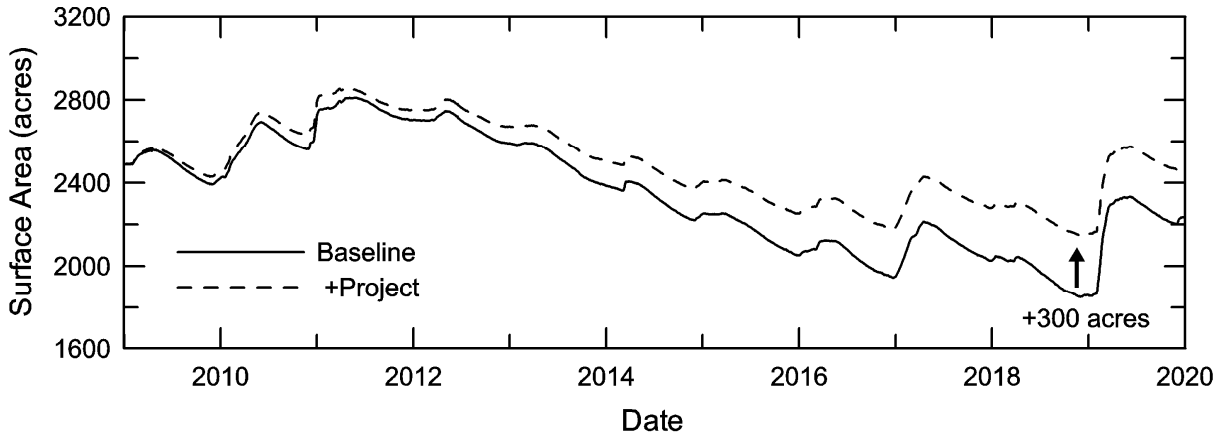

Figure 28. Predicted lake surface area over 2009-2019: baseline and with project.

C. TDS

Addition of 1,920 AFY of Alternative 1 effluent with a TDS of 450 mg/L, predictably increased TDS relative to the Baseline scenario, while Alternative 2 effluent yielded predicted TDS concentrations similar to those present in 2009-2019, and Alternative 3 effluent lowered TDS levels below the Baseline scenario (Figure 29; Table 19).

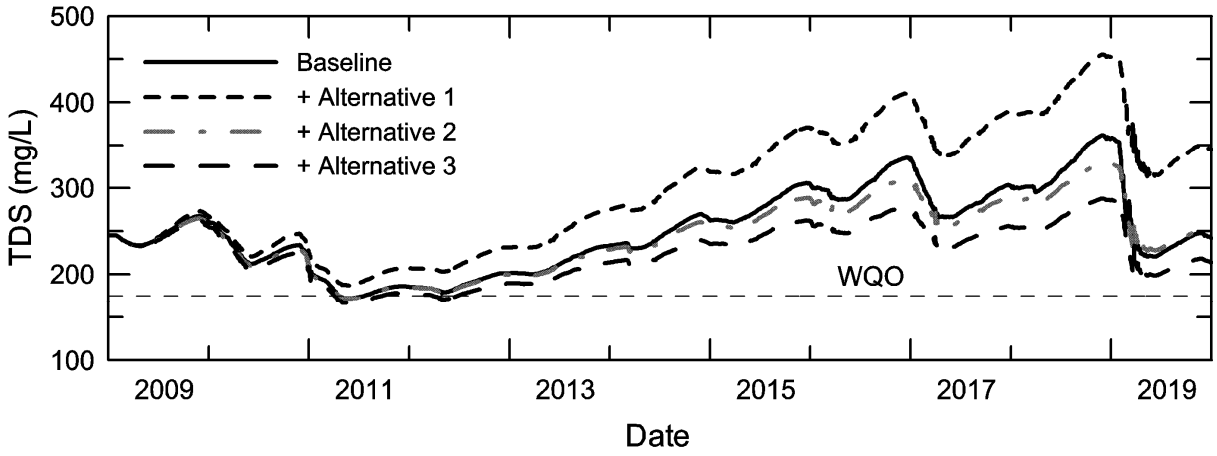

Figure 29. Predicted TDS concentrations over 2009-2019: baseline and with project.

Predicted TDS for the Baseline scenario exceeded the WQO of 175 mg/l (dashed line) 97.6% of the time over 2009-2019, a frequency equivalent to that of the Alternative 2 treatment scenario, and greater than that with Alternative 3 treatment scenario (Table 19).

Table 19. Summary of TDS concentrations for 2009-2019 under natural conditions and with project.

Scenario	Average TDS (mg/L)	Range TDS (mg/L)	WQO Exceedance Frequency (%)
Baseline	251	172-362	97.6
Alternative 1	300	187-455	100.0
Alternative 2	244	171-329	97.6
Alternative 3	226	166-287	93.3

D. Nutrients and Chlorophyll-a

Nutrients entering the lake add to the inventory of nutrients already present, which are subject to a wide array of biogeochemical processes. To help put nutrients derived from supplemental water of differing levels of treatment into context, it is useful to consider their composition and loading relative to watershed sources. Median watershed concentrations and concentrations in Alternative 1-3 effluents are provided in Table 20. Alternative 1 effluent substantially exceeds median watershed concentrations for virtually all nutrients, while addition of RO in Alternatives 2 and 3 lowers concentrations, often to levels comparable to or in some cases below median watershed levels.

Table 20. Comparison of nutrient concentrations in watershed runoff and supplemental water with the three Treatment Alternatives.

	Median Watershed Concentrations (mg/L)					Nutrient Concentrations (mg/L)		
Variable	Boulder Cr	Grout Cr	Knickerb Cr	Rathbun Cr	Summit Cr	Alt 1	Alt 2	Alt 3
NO_3-N	0.05	0.183	0.13	0.419	0.19	0.6	0.2	0.05
NH_4-N	0.011	0.01	0.015	0.015	0.015	0.2	0.1	0.05
PO_4-P	0.007	0.015	0.038	0.038	0.021	0.25	0.06	0.02
Total N	0.184	0.378	0.312	0.716	0.481	2.2	1.1	0.6
Total P	0.009	0.023	0.055	0.055	0.075	0.5	0.1	0.03
TN/TP	20.4	16.4	5.7	13.0	6.4	4.4	11	20

Normalizing project concentrations as ratios to median watershed concentrations allows comparison of relative enrichment factors for supplemental water (concentration basis) (Table 21):

Table 21. Concentration enrichment factors (supplemental/watershed).

	Concentration Enrichment Factor		
Variable	Alternative 1	Alternative 2	Alternative 3
NO_3-N	3.3	1.1	0.3
NH_4-N	13.3	6.7	3.3
PO_4-P	11.9	1.6	0.5
Total N	5.8	2.3	0.8
Total P	9.1	1.8	0.4

One thus recognizes that Alternative 1 (TIN & TP Removal) effluent represents about 6-times and 9-times greater concentrations of TN and TP, respectively, compared with the watershed, while Alternative 2 (70% RO) is on the order of about 1-2 times higher concentrations, and Alternative 3 (100% RO) is significantly lower than typical concentrations of most forms of nutrients delivered from the watershed (Table 21). Importantly, Alternative 1 effluent is not only much higher in nutrient concentrations, it also has a very low TN:TP ratio (Table 20), that could potentially favor N_2-fixing blue-green algae.

Simulations demonstrated that water quality in the Lake is broadly similar between the Baseline scenario and the Alternative 2 and 3 treatment scenarios, but is significantly degraded with Alternative 1 effluent, with marked predicted increases in TP, TN, and chlorophyll-a concentrations (Figure 30).

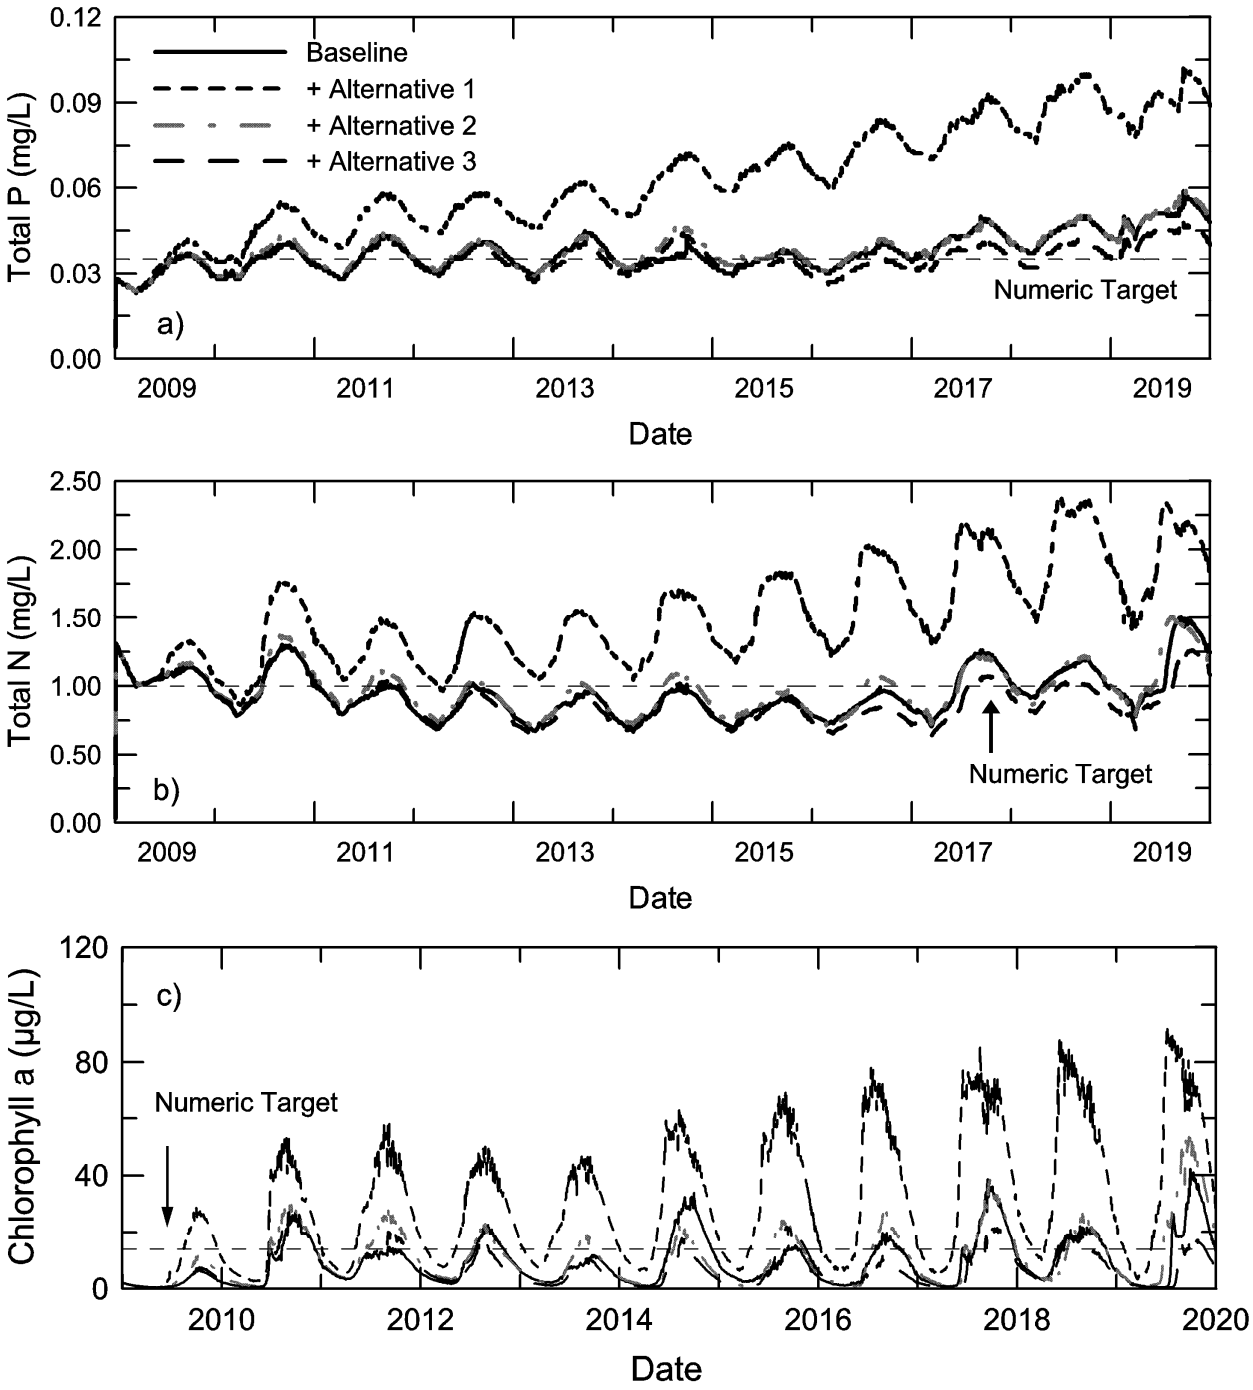

Figure 30. Predicted concentrations of a) total P, b) total N, and c) chlorophyll-a at TMDL station #2 (photic zone).

Supplementation with Alternative 1 effluent also significantly increased littoral plant production, often doubling peak values relative to that predicted under the Baseline scenario and with treatment alternatives 2 and 3 (Figure 31).

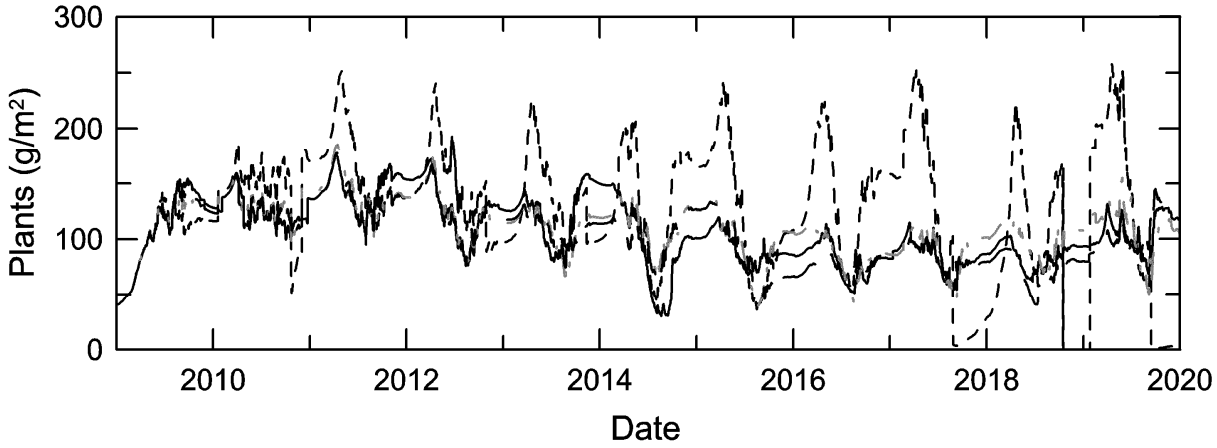

Figure 31. Predicted plant biomass at TMDL station #2 (photic zone). Legend shown in Fig. 30a.

Average concentrations at TMDL station #2 (Gilner Point) for the 11-yr simulation period highlight substantial predicted increases in total P, PO_4-P, and total N resulting from supplementation with Alternative 1 effluent (Table 20). The large increase in P concentrations also yielded a substantial increase in predicted average chlorophyll-a concentration (30.5 vs 9.3 µg/L). Supplementation with Alternative 1 effluent also increased TIN concentrations compared with the Baseline scenario and increased (non-phytoplankton) plant production. Supplementation with Alternative 2 effluent yielded predicted average water quality quite similar to the Baseline scenario, while supplementation with Alternative 3 effluent was predicted to improve average water quality somewhat (Table 22).

Table 22. Average concentrations of nutrients and chlorophyll-a for 2009-2019 period under the Baseline scenario and with supplementation with water from the three Treatment Alternatives.

Scenario	Total N (mg/L)	Total P (mg/L)	Chl a (µg/L)	PO_4-P (µg/L)	TIN (mg/L)	Plants (g/m^2)
Baseline	0.948	0.037	9.3	3.5	0.049	106.9
Alternative 1	1.511	0.063	30.5	7.8	0.120	126.3
Alternative 2	0.979	0.038	10.9	3.6	0.047	110.2
Alternative 3	0.894	0.035	7.1	3.3	0.046	103.1

Supplementation of treated effluent from the BBARWA WWTP is thus predicted to yield different water quality in Big Bear Lake depending upon effluent water quality. Supplementation with Alternative 1 effluent is predicted to substantially increase lake total P and PO_4-P concentrations, which may also increase N_2-fixing blue-green algae, as well as increase epiphyte and macrophyte production. Supplementation with Alternative 2 effluent is predicted to yield water quality conditions similar to natural conditions, while providing increased lake volume, lake surface area, and additional (non-planktonic) plant biomass. Further treatment of effluent in Alternative 3 was predicted to slightly improve water quality compared with that predicted for the 2009-2019 Baseline scenario.

Cumulative distribution functions for basin-wide volume-averaged concentrations of TP and TN highlight the substantial increase in nutrients that would result from the addition of Alternative

1 effluent, while also demonstrating that Alternative 2 effluent is predicted to yield nutrient levels similar to predicted 2009-2019 levels, while supplementation with Alternative 3 effluent is predicted to yield slightly improved (lower) concentrations (Figure 32).

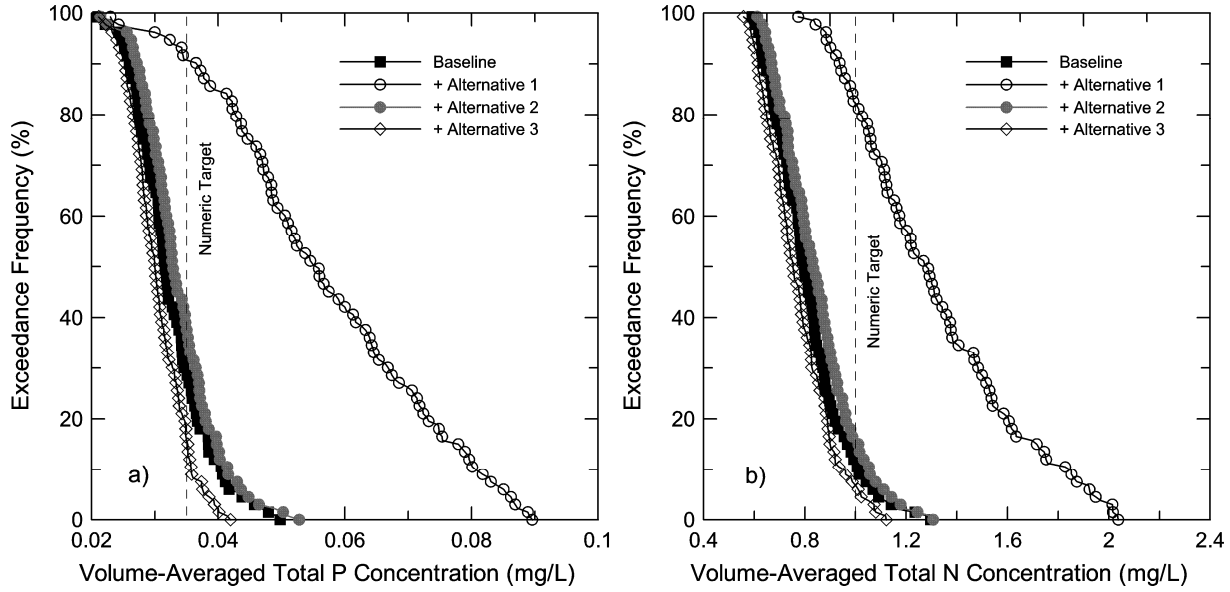

Figure 32. Cumulative distribution functions for predicted baseline and supplementation scenarios of volume-weighted concentrations of a) total P and b) total N.

Summary

Supplementation of natural flows with 1,920 af/yr of Replenish Big Bear water was predicted to add about 0.2 m annually to the lake relative to levels observed in 2009-2019 (baseline), and which accrued over time such that the lake was predicted to be 1.7 m higher in late 2018 compared to the level present at that time. Supplementation also increased lake volume and surface area, with lake area about 300 acres (16%) larger in late 2018 compared with actual area (approximately 2200 acres vs 1900 acres, respectively). Addition of 1,920 af/yr of Alternative 1 water significantly increased TDS levels in the lake, increasing average predicted TDS from 251 mg/L for the baseline (natural) condition for 2009-2019 to 300 mg/L, while Alternatives 2 and 3 were predicted to yield slightly lower average TDS concentrations of 244 and 226 mg/L, respectively. Exceedance of the TDS water quality objective of 175 mg/L was predicted to occur 97.6% of the time for both the baseline condition and for Alternative 2, while exceedance frequency increased to 100% for Alternative 1 and was reduced to 93.3% for Alternative 3.

Nutrient concentrations in the Replenish Big Bear water varied markedly with treatment, with total N and total P concentrations in Alternative 1 being about 6-9x higher than median watershed concentrations, while concentrations in Alternative 2 were projected to be 1.8-2.3x larger and Alternative 3 being about 0.4-0.8x that of median watershed values. The increased nutrient loading from Alternative 1 had a strongly detrimental effect on water quality, increasing average concentrations over 2009-2019 baseline of total N by about 50%, total P by 70%, and chlorophyll-a by 300%. In comparison, further treatment of effluent yielded average

concentrations comparable to (Alternative 2) or slightly improved (Alternative 3) relative to the baseline (natural no-project) condition.

V. PREDICTED LONG-TERM FUTURE CONDITIONS WITH REPLENISH BIG BEAR PROJECT

Simulations were extended from the reference period (2009-2019) to include 30 additional years, for a total of 41 simulation years that yielded potential trajectories for water level, area, TDS, and nutrients out to the beginning of 2050. As previously noted, the model requires extensive data for meteorological conditions (air temperature, dewpoint temperature, wind speed, wind direction, cloud cover, and solar radiation), as well as water inflows, outflows, and withdrawals. While hourly weather forecasts are available 7-10 days in advance from the National Weather Service (NWS) and 5-10 day flow forecasts are available for limited gaged stations from the NWS River Forecast Centers, we obviously do not know *a priori* these detailed meteorological and hydrological conditions for the next 30 years. Similarly, while downscaled global climate models provide some projections about trends in air temperature and precipitation, they do not provide information with sufficient resolution to allow direct use in our simulations.

Given these constraints, existing meteorological and flow data for 2009-2019 were used as the basis for forecasts. (An effort was made to expand the meteorological record to include additional years, but available weather data for the Big Bear Airport only go back to April 2007, thus providing only one additional full year of record, so existing data were used.) The 2009-2019 period included record or near record air temperatures and intervals of both extreme drought and very high precipitation/runoff that captured much of the anticipated inter-annual variability in meteorology and hydrology (e.g., Table 23). For example, average precipitation over 2009-2019 period was not statistically significantly different than that of the past 43 years (e.g., 31.7±15.6 vs 34.8±14.7 in/yr at Bear Valley Dam). Precipitation was better described as log-normally distributed; however, with geometric mean values very similar to median values, and both being slightly lower (reflecting increased prevalence of drought) but well-captured in the 2009-2019 dataset. Perhaps more importantly, minimum and maximum values for the 2009-2019 period were also similar to the larger 1977-2019 dataset (e.g., the highest annual precipitation at the Big Bear Community Services District (BBCCSD) was recorded in 2010, within the 2009-2019 record).

Table 23. Annual precipitation (calendar year) recorded at Bear Valley Dam and BBCCSD. (Water Master, 2019).

Precipitation (in/yr)	Bear Valley Dam		BBCCSD	
	1977-2019	2009-2019	1977-2019	2009-2019
Average	34.8	31.7	14.9	17.5
Geometric Mean	31.6	29.1	13.3	16.3
Median	31.8	27.8	14.1	14.8
Minimum	13.2	14.4	3.8	8.2
Maximum	73.8	64.1	33.2	33.2

Assuming that 2009-2019 is broadly representative of likely future meteorological and hydrologic conditions, Monte Carlo techniques were used to randomly select 100 different 30-year annual records from this set of data. Thus, any given future year was assumed to essentially have a 1-in-11 chance of looking like any one of the years from the 2009-2019 period in terms of meteorological conditions, inflows, withdrawals, and releases for downstream flow

requirements. Impacts of climate change were considered; air temperature increases would increase evaporation losses from lake, but also likely yield more rain and rain-on-snow events that would increase runoff and inflows to lake. Without detailed watershed modeling, it is not possible to resolve these conflicting impacts on the water budget for the lake, so for the purposes of this analysis, they were assumed to cancel out. The Monte Carlo analysis yielded 30-year average flow rates that ranged from 6,891 to 15,115 af/yr (Figure 33). Individual year flow rates varied more widely, ranging from 1,961 – 27,579 af/yr (not shown).

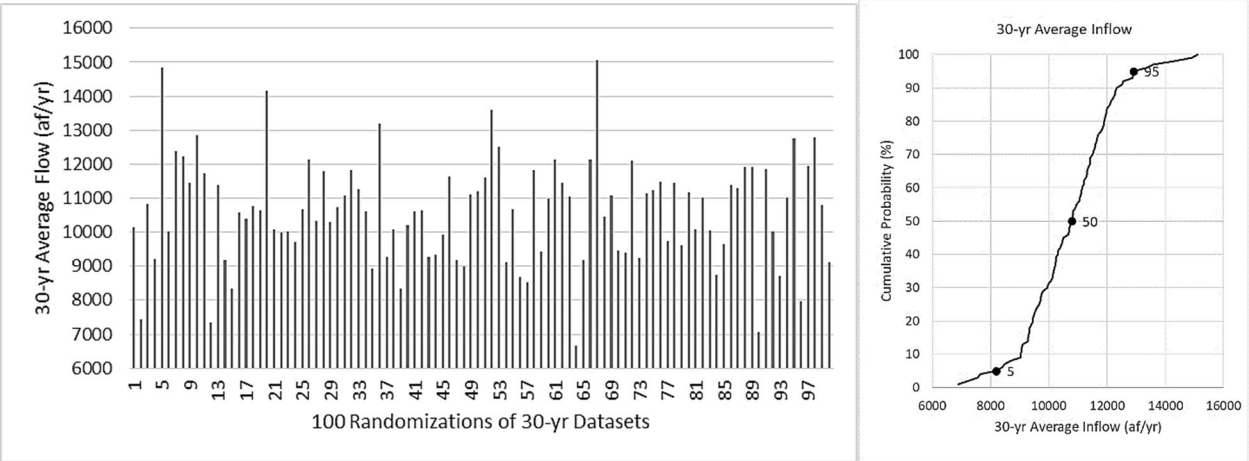

Figure 33. Thirty year average flow rates for 100 random datasets.

From this dataset (Figure 33), three hydrologic scenarios were selected for further analysis corresponding to the 5th-percentile, 50th-percentile (median), and 95th-percentile 30-yr average flow rates. The 5th-percentile corresponds to an average inflow rate of 8,646 af/yr and represents extended drought, not unlike that present in the 1950's-60's, while the 50th-percentile hydrologic scenario corresponds to intervals of both high runoff and drought, comparable to 2009-2019 (average annual inflow of 10,595 af/yr), and the 95th-percentile represents a period of protracted above average rainfall and runoff (average annual inflow of 12,225 af/yr). Cumulative inflows for these 3 hydrologic scenarios are presented in Figure 34. The corresponding meteorological, outflow and withdrawal conditions were used as input for CE-QUAL-W2 simulations. The 3 simulations represent forecasts of conditions subject to the temporal boundary conditions (inflows, meteorological conditions, etc.), and thus are not predictive of conditions at specific points of time in the future. On that basis, results are presented as cumulative distribution functions rather than time-series to convey information in a statistical-probabilistic framework rather than as strict forecasts in time. Lake properties are contrasted between baseline conditions under the 3 hydrologic scenarios and with implementation of the Replenish Big Bear project.

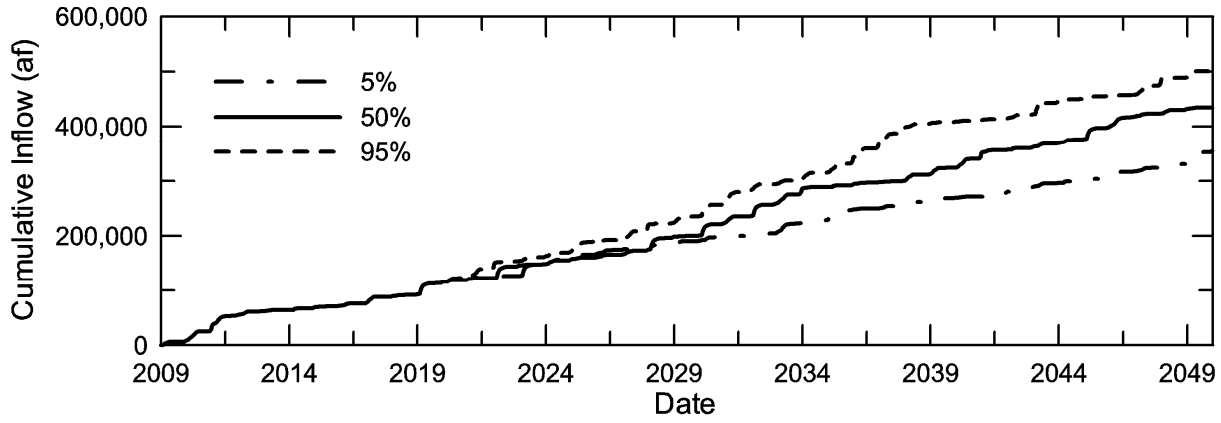

Figure 34. Cumulative inflows under 5th-, 50th- and 95th-percentile 30-yr average hydrologic scenarios.

A. Lake Surface Elevation

The 3 hydrologic scenarios had pronounced effects on predicted lake levels, with the 5th-percentile (chronic drought) scenario yielding elevations as low as 2044.9 m above MSL and a median elevation of 2048.8 m (Figure 35a). The 50th- and 95th-percentile hydrologic scenarios yielded predictably higher lake levels (e.g., median levels of 2052.2 and 2053.1 m, respectively) (Figure 35a). Supplementation with 1,920 af/yr of Replenish Big Bear water markedly increased lake levels, *e.g.*, raising the minimum level for 5th-percentile scenario by up to 4.6 m and increasing median level from 2048.8 m for baseline to 2052.0 m (Figure 35b).

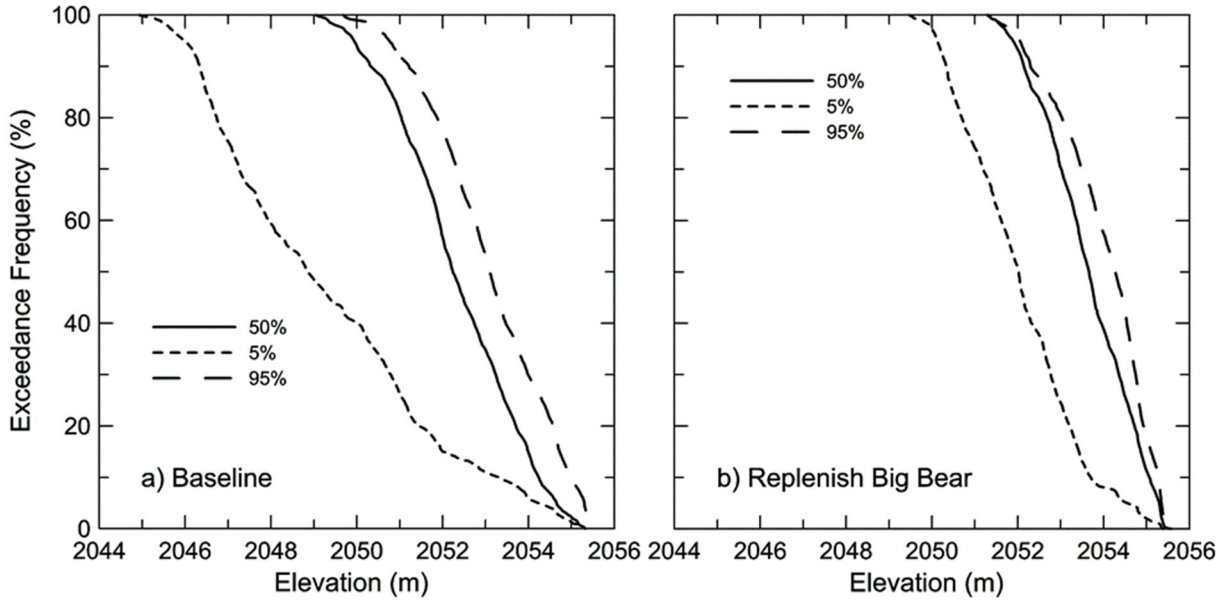

Figure 35. CDFs of predicted lake elevations at 5th-, 50th- and 95th-percentile hydrologic scenarios for a) baseline conditions and b) supplementation with Replenish Big Bear water.

B. Lake Volume

Supplementation also substantially increased lake volumes, with volumes potentially as low as 6,000 af and a median volume of about 23,000 af for the 5th-percentile (drought) scenario (Figure 36). Supplementation with Replenish Big Bear water resulted in significant increases in lake volume for the other hydrologic scenarios as well (Figure 36).

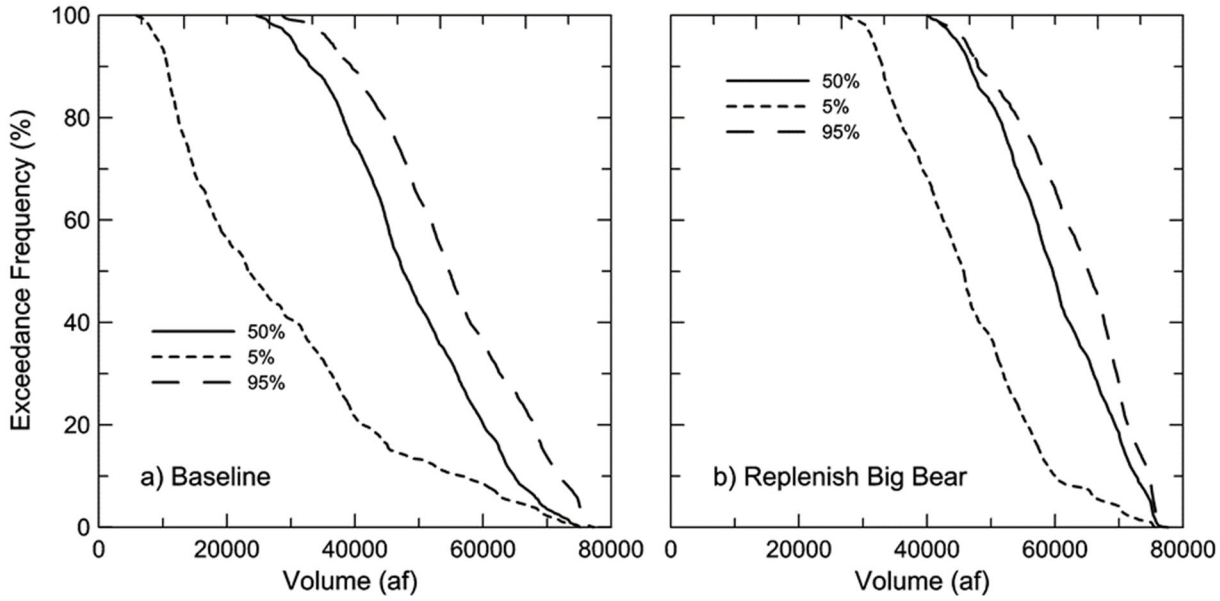

Figure 36. CDFs of predicted lake volumes at 5th-, 50th- and 95th-percentile hydrologic scenarios for a) baseline conditions and b) supplementation with Replenish Big Bear water.

C. Lake Surface Area

The 5th-percentile hydrologic scenario also yielded very low lake surface areas, potentially <1000 acres and a median area of about 1700 acres (Figure 37a). The minimum predicted lake surface areas were about 2x larger and median surface areas were approximately 2300 and 2500 af for the 50th- and 95th-percentile hydrologic scenarios, respectively. Supplementation substantially increased lake area, shifting all CDFs to higher area values (Figure 37b). This can be seen more graphically in Figure 38, where the areas corresponding to the minimum and 75% exceedance frequencies (predicted to occur 25% of the time under the simulated protracted drought condition) are projected onto the natural lake boundary for the baseline and with project. At the minimum area, the lake divides into the impounded area behind the dam and a 2nd very shallow mid-basin, while the Project is able to maintain an extensive and contiguous lake area through the main body of the lake (Figure 38a). A considerable additional area is also maintained at the 75% exceedance frequency with supplementation (Figure 38b).

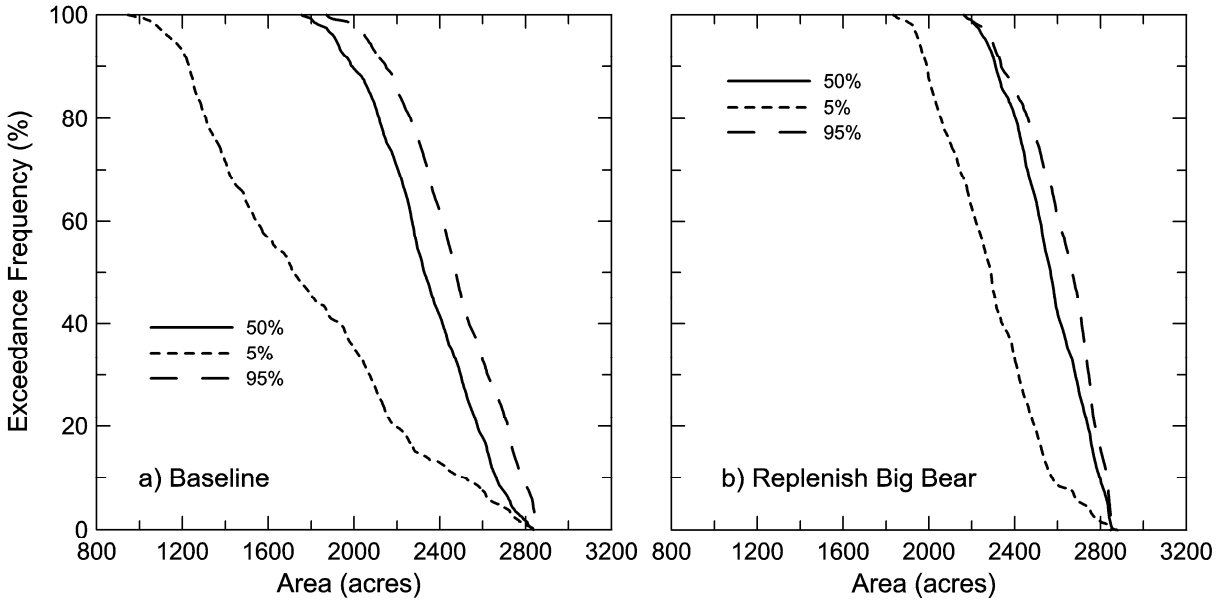

Figure 37. CDFs of predicted lake areas at 5th-,50th- and 95th-percentile hydrologic scenarios for a) baseline conditions and b) supplementation with Replenish Big Bear water.

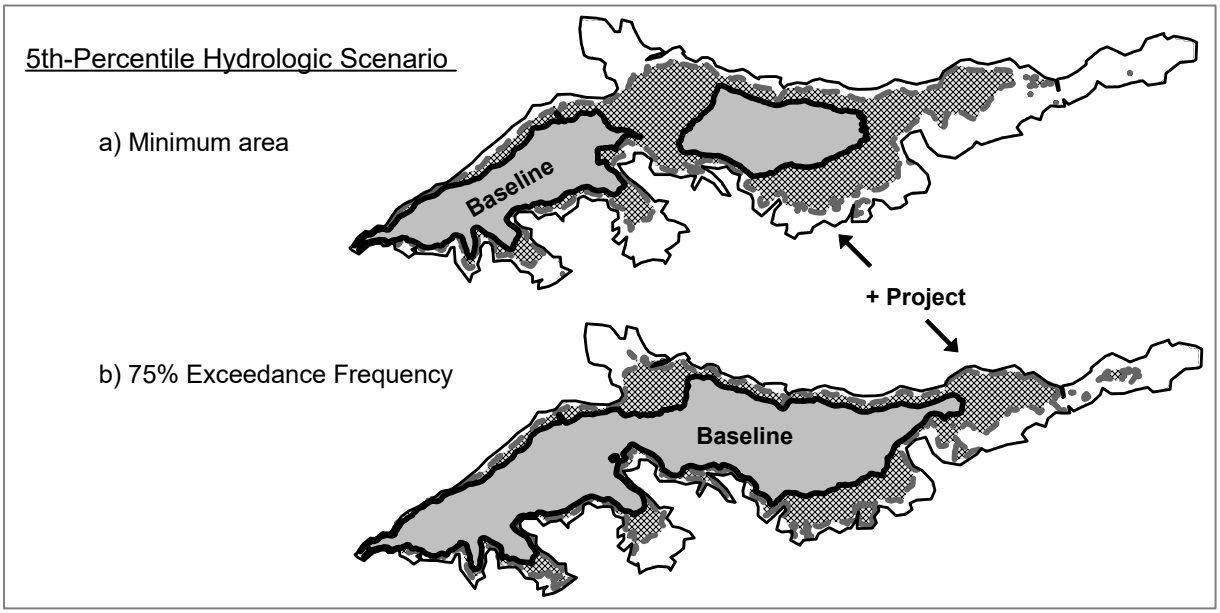

Figure 38. Lake surface under 5th-percentile flows (protracted drought) depicting areas under baseline conditions (solid gray) and with project (cross-hatched) at a) minimum area and b) 75% exceedance frequency (predicted to occur 25% of the time under the simulated protracted drought condition).

D. Total Dissolved Solids

The concentrations of TDS in Big Bear Lake vary naturally as a function of lake level as a result of runoff inputs and evapoconcentration. Thus, predicted TDS concentrations were greatest for the 5th-percentile hydrologic scenario (protracted drought) and lower for the 50th- and 95th-percentile hydrologic scenarios (Figure 39a). Unlike lake elevation, volume and area which are independent of the type of effluent treatment, predicted TDS concentrations in the lake are quite sensitive to it (Figure 39b-d).

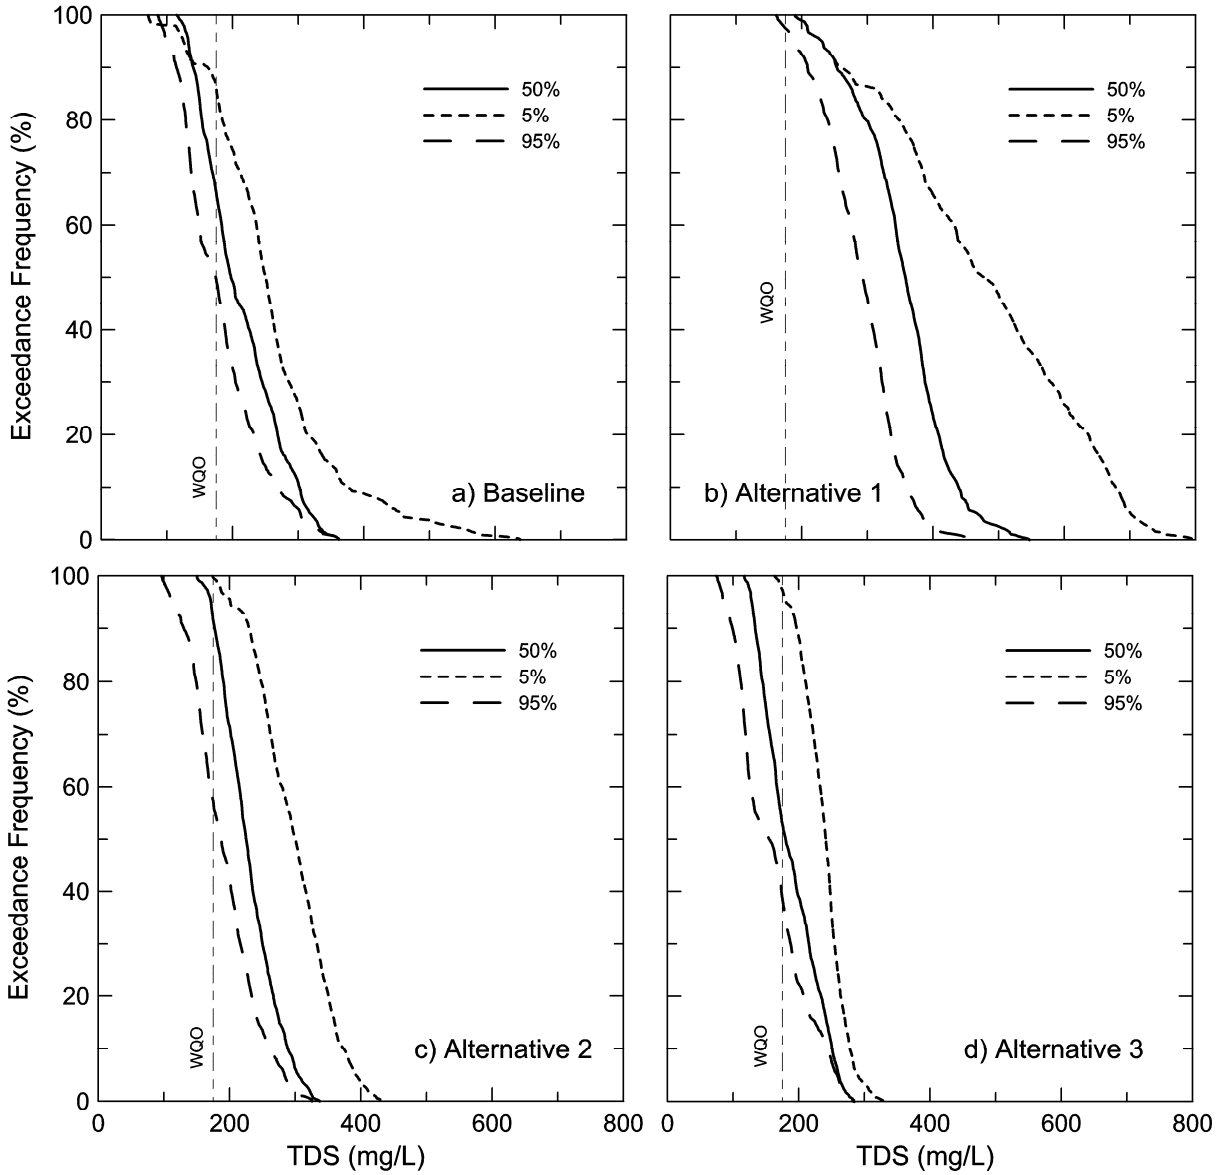

Figure 39. CDFs of predicted lake TDS at 5th-,50th- and 95th-percentile flows for a) baseline conditions, and supplementation with b) Alternative 1, c) Alternative 2 and d) Alternative 3 water.

Alternative 1 treatment, involving only nutrient removal, yielded high concentrations of TDS that was predicted to exceed the water quality objective by wide margins (Figure 38b), while Alternative 2 shifted CDFs from baseline to slightly higher TDS levels, and the highest level of treatment (Alternative 3) yielded slightly lowered concentrations relative to Baseline scenario (Figure 39c,d).

E. Total P

Total P concentrations for the baseline condition were predicted to vary under the 3 hydrologic scenarios, exceeding 0.05 mg/L with some frequency under the drought scenario (Figure 40a).

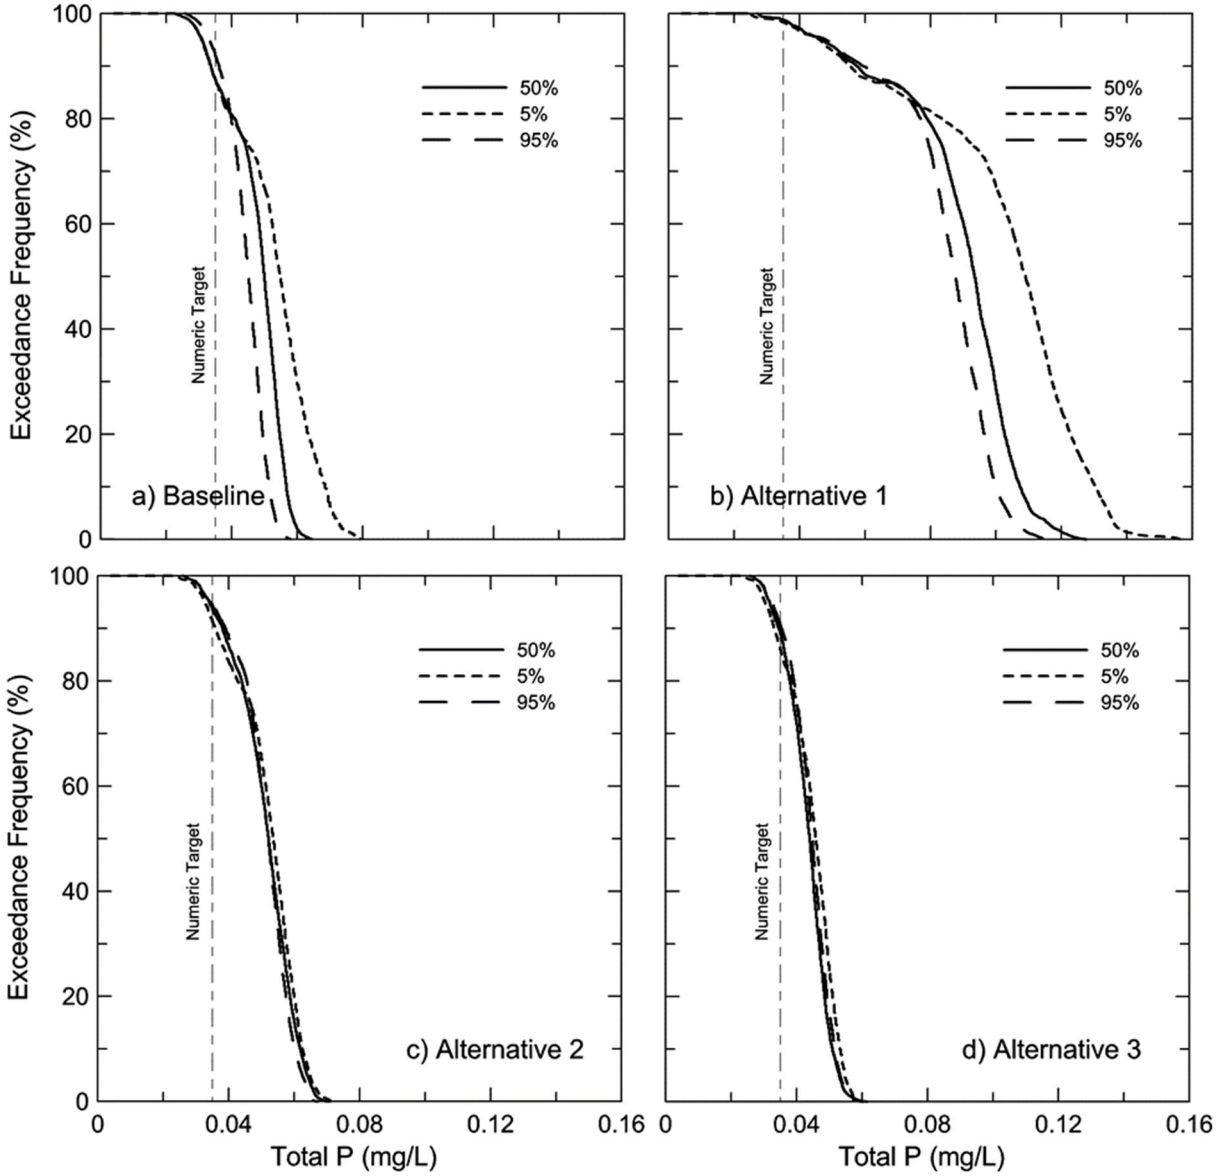

Figure 40. CDFs of predicted total P levels at 5th-, 50th- and 95th-percentile hydrologic scenarios for a) Baseline, and supplementation with b) Alternative 1, c) Alternative 2 and d) Alternative 3 water.

As noted in simulations for 2009-2019, supplementation with Replenish Big Bear effluent substantially degraded predicted water quality, and increased total P (Figure 40b), as well as total N (Figure 41b) and chlorophyll-a (Fig. 42b). Supplementation with higher quality Alternative 2 and 3 water reduced natural variability and provided comparable or lower levels (Figure 40c,d).

F. Total N

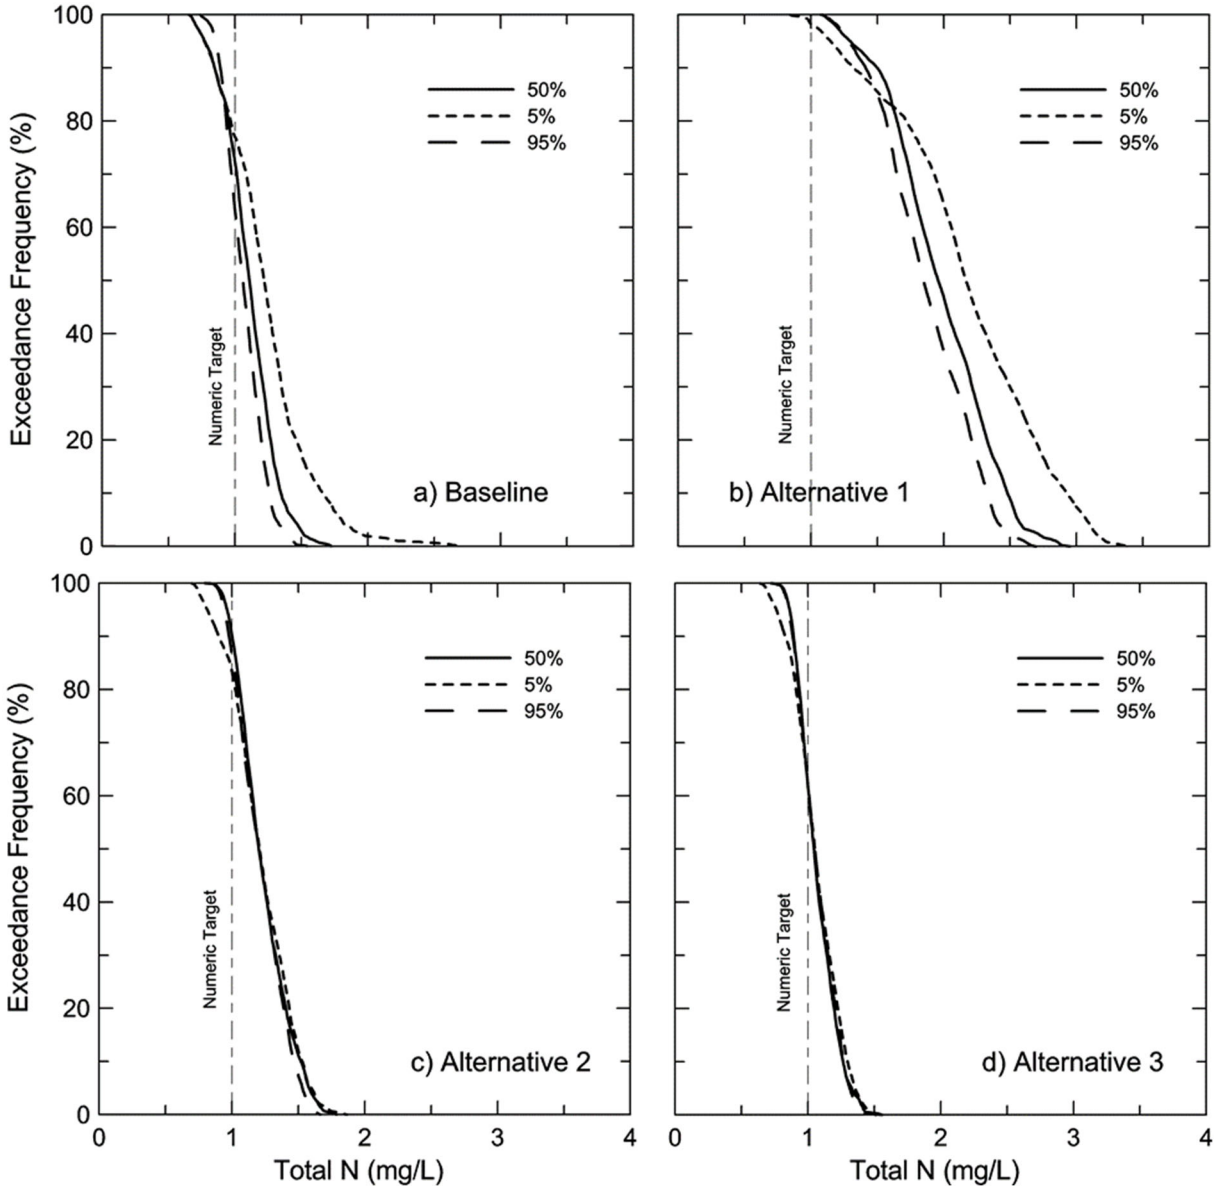

Figure 41. CDFs of predicted total N levels at 5th-, 50th- and 95th-percentile hydrologic scenarios for a) baseline conditions, and supplementation with b) Alternative 1, c) Alternative 2 and d) Alternative 3 water.

Predicted total N concentrations (Figure 41) followed the same trends as total P (Figure 40), with Alternative 1 significantly increasing concentrations, while Alternatives 2 and 3 reduced variability in baseline case due to stabilization of lake level with high quality water (Figure 41).

G. Chlorophyll-a

Chlorophyll-a concentrations followed similar trends as noted for total P and total N, with a >5x increase in median predicted concentrations with Alternative 1 compared with baseline, while Alternatives 2 and 3 yielded comparable or slightly higher predicted concentrations (Figure 42).

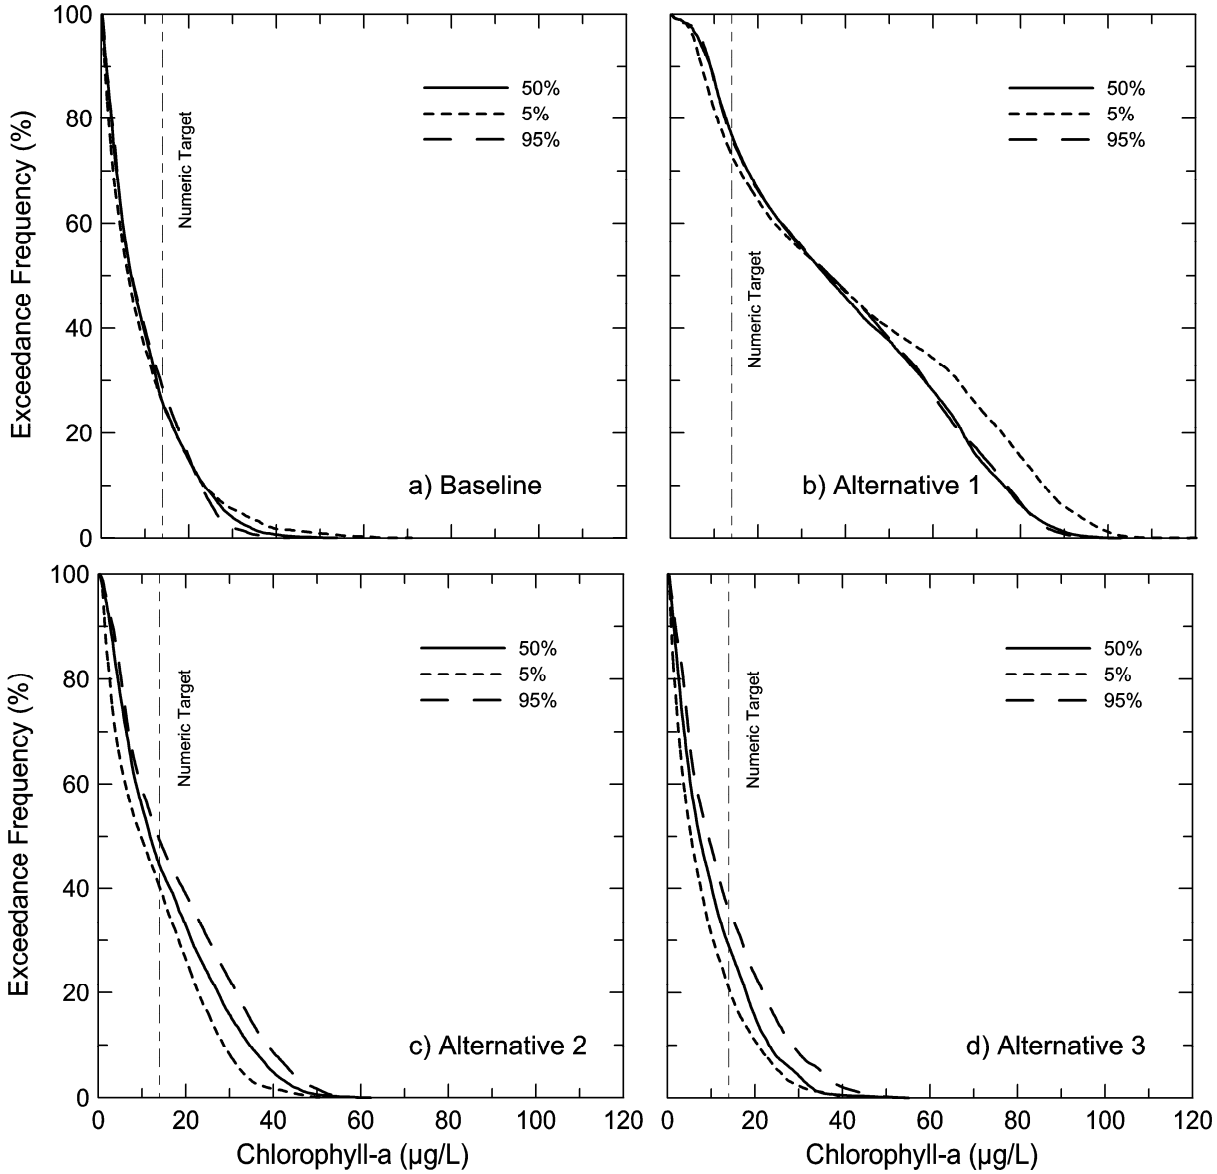

Figure 42. CDFs of predicted chlorophyll-a levels at 5th-, 50th- and 95th-percentile hydrologic scenarios for a) Baseline, and supplementation with b) Alternative 1, c) Alternative 2 and d) Alternative 3 water.

CDF Summary

CDFs convey a great deal of information, although it is often not easy to readily resolve differences across multiple graphs. Median lake dimensions for the 3 different hydrologic scenarios with and without supplementation with water from the Replenish Big Bear project from Figures 34-36 are summarized in Table 24.

Table 24. Influence of hydrologic scenarios and supplementation on median lake dimensions.

Parameter	Scenario	5th-Percentile	50th-Percentile	95th-Percentile
Elevation (m)	Baseline	2048.9	2052.2	2053.1
	+Project	2052.0 (+3.2)	2053.7 (+2.2)	2054.3 (+1.6)
Volume (af)	Baseline	23,404	47,536	54,724
	+Project	45,746 (+22,342)	59,664 (+12,128)	65,204 (+10,480)
Area (acres)	Baseline	1717	2328	2474
	+Project	2290 (+572)	2568 (+240)	2669 (+195)

Median concentrations of TDS, total N, total P and chlorophyll-a under the different hydrologic scenarios and levels of treatment are summarized in Table 25. As evident in the CDFs, the level of treatment of the supplemental water substantially affects the resulting water quality in the lake. Treated effluent with nutrient removal (Alternative 1), without additional treatment, offsets or other strategies, is predicted to have significant negative impacts to water quality in the lake, nearly doubling median concentrations of total P and total N, and increasing median chlorophyll-a concentrations by >5x relative to levels predicted for the natural (baseline) scenario (Table 25). Further advanced treatment of effluent (Alternatives 2 and 3), however, yielded predicted water quality broadly similar to or slightly better than the baseline case (Table 25).

Table 25. Influence of hydrologic scenarios and supplementation with alternative levels of treatment on predicted median concentrations of TDS, total N, total P and chlorophyll-a.

Parameter	Scenario	5th-Percentile	50th-Percentile	95th-Percentile
TDS (mg/L)	Baseline	250	198	175
	Alternative 1	478	358	293
	Alternative 2	300	225	187
	Alternative 3	241	180	155
Total P (mg/L)	Baseline	0.055	0.050	0.045
	Alternative 1	0.109	0.094	0.088
	Alternative 2	0.054	0.052	0.052
	Alternative 3	0.046	0.044	0.045
Total N (mg/L)	Baseline	1.22	1.11	1.06
	Alternative 1	2.17	1.96	1.85
	Alternative 2	1.21	1.20	1.20
	Alternative 3	1.05	1.05	1.05
Chlorophyll-a (µg/L)	Baseline	6.2	6.9	7.0
	Alternative 1	36.1	35.6	36.5
	Alternative 2	9.7	11.9	13.7
	Alternative 3	5.4	7.3	9.4

Summary

Simulations for 2009-2019 were extended to 2050 to evaluate possible long-term conditions in the lake under natural hydrologic variability with and without supplemental water from

Replenish Big Bear. Three hydrologic scenarios representing the 5th-, 50th- and 95th-percentile 30 year average annual flow records were used for predictions of future conditions in the lake. The 5th-percentile corresponded to an average inflow rate of 8,646 af/yr and represents extended drought, while the 50th-percentile (median) corresponded to intervals of both high runoff and drought comparable to 2009-2019 (average annual inflow of 10,595 af/yr), and the 95th-percentile represented a period of protracted above average rainfall and runoff (average annual inflow of 12,225 af/yr).

Supplementation with Replenish Big Bear was predicted to influence long-term (2009-2050) conditions in the lake which varied under the 3 hydrologic scenarios. Under the 50th-percentile hydrologic scenario, Replenish Big Bear was predicted to increase average lake level by 1.5 m, lake volume by nearly 13,000 af, and lake area by 260 acres relative to the predicted long-term baseline (no-project) condition. Water quality varied with level of effluent treatment, with Alternative 1 nearly doubling predicted long-term average concentrations of TDS, total P and total N and quadrupling average predicted chlorophyll-a levels. Long-term simulations indicate slight increases in average TDS, total P and total N and modest increase in chlorophyll-a for Alternative 2, and generally slight reductions or no significant change in concentrations with Alternative 3. Supplementation was predicted to have more substantial effects under the 5th-percentile hydrologic (drought) scenario, providing an average increase in lake level of 3.4 m, increase in volume of 16,104 af, and an additional average 638 surface acres (about 40% increase) relative to baseline. As with the 50th-percentile hydrologic scenario, supplementation with Alternative 1 effluent substantially degraded lake water quality, while further treatment as provided in Alternatives 2 and 3 yielded comparable or slightly improved water quality in the lake. Effects of Replenish Big Bear were more modest at the 95th-percentile runoff scenario, when supplementation is less important, owing to the lower overall contributions of water and TDS and nutrients relative to the watershed.

VI. ROUTING OF SUPPLEMENTAL WATER THROUGH STANFIELD MARSH

Simulations involved the delivery of Replenish Big Bear project water through Stanfield Marsh and into the main body of the lake. Wetlands are often very good at improving water quality by filtering and settling out of particulate matter, biological uptake of dissolved forms of nutrients, and under favorable conditions also denitrification and loss of NO_3-N to the atmosphere. Stanfield Marsh was predicted to be an effective sink for total P in supplemental water with Treatment Alternatives 1 and 2 but was a modest source of total P for Alternative 3 water (Figure 43, Table 26).

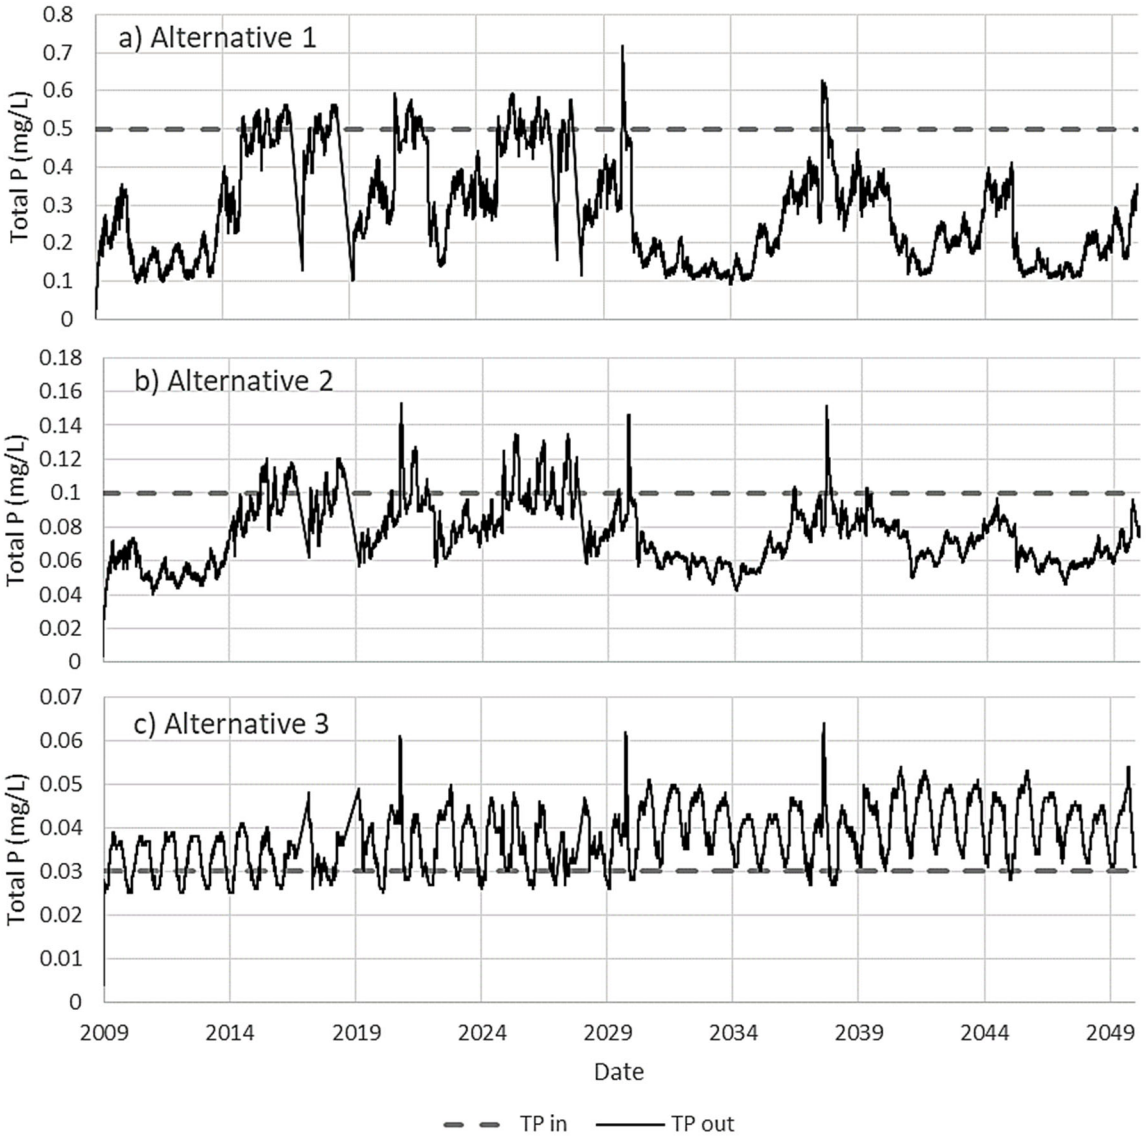

Figure 43. Total P concentrations into and out of Stanfield Marsh: a) Alternative 1, b) Alternative 2, and c) Alternative 3.

Interestingly, the marsh was predicted to be a net source of N for all 3 treatment scenarios; the basis for this is not entirely clear at this time, but sediment mineralization and potentially some N_2-fixation may be occurring during periods of intense primary production that could increase the total N concentration. Stabilization of the water level within the marsh through some hydraulic control would presumably increase nutrient retention and could promote denitrification, although additional work is needed to understand the dynamics within the Marsh, especially given natural variations in lake levels and intervals of wetting and desiccation.

Table 26. Predicted average total P and total N removal in Stanfield Marsh.

	Alternative 1		Alternative 2		Alternative 3	
	% Removal	kg/yr	% Removal	kg/yr	% Removal	kg/yr
Total P	14.8	175	8.4	20	-10.3	-7
Total N	-22.5	-1174	-17.0	-442	-19.0	-270

Summary

Simulations indicate net removal of total P from Alternative 1 and Alternative 2 effluents during flow through Stanfield Marsh, while the Marsh was predicted to be a modest source of total P to Alternative 3 water with very low influent concentrations. Interestingly, the Marsh was predicted to be a source of total N across all levels of treatment, due presumably to sediment decay, some N_2-fixation and subsequent decay in response high PO_4-P concentrations and high TN:TP ratios in the effluent. Further work is needed, however, to better understand the role of the Marsh as a net sink and/or source for nutrients.

VII. SUMMARY

Lake conditions and water quality in Big Bear Lake varied significantly over 2009-2019, with wide natural variations in lake level, volume and surface area, as well as concentrations of TDS, nutrients and chlorophyll-a. Statistical, machine learning and hypolimnetic mass balance analyses provided valuable new information about water quality in Big Bear Lake, while CE-QUAL-W2 was able to reproduce observed trends in lake conditions. Supplementation of natural runoff with Replenish Big Bear water significantly increased lake levels, volumes and surface areas, especially during periods of drought, with resulting recreational, aesthetic, community and related benefits. The level of treatment had dramatic effects on water quality, however. Nutrient removal (Alternative 1) was not sufficient to protect water quality in Big Bear Lake, although nutrient removal with further treatment (Alternatives 2 and 3) was predicted to yield water quality comparable to or slightly improved relative to baseline conditions.

Introduction

It was previously noted that water quality was predicted to vary markedly with the level of treatment of added Replenish Big Bear (RBB) recycled water, with Alternative 1 (TIN and TP removal) significantly degrading water quality in Big Bear Lake relative to predicted baseline conditions, while Alternative 2 (70% RO) modestly increased average predicted concentrations of TN, TP and chlorophyll-a, and Alternative 3 (100% RO) was predicted to slightly improve average water quality for the 2009-2019 period (Anderson, 2021, Table 22). Long-term simulations for different hydrologic scenarios yielded similar results, with 100% RO yielding predicted water quality typically comparable to baseline conditions. Notwithstanding, some subtle differences were observed between predicted median baseline concentrations and those for Alternative 3 which assumed steady annual flows of 1920 af/yr of 100% RO water (Anderson, 2021, Table 25).

Recent engineering work indicates that slightly higher inflows, up to 2210 af/yr, can be attained by the Replenish Big Bear project by employing additional brine minimization technology (Table 1). Note that a portion of the water produced by RBB may be discharged to Shay Pond and the earlier "Alternative 3" scenario had excluded those flows (up to 80 af/yr) from the analysis. However, to be conservative for permitting purposes, this analysis is based on discharging all of the recycled water produced to the Lake.

Table 1. Initial and recently updated Replenish Big Bear (RBB) flow projections.

Scenario	**Annual RBB Inflow (af)**	**Daily RBB Inflow (MGD)**
Baseline	0	0
Alternative 3 [(a)]	1920	1.71
High Flow (99% recovery) [(b)]	2210	1.57 – 2.18
Mid Flow (90% recovery) [(b)]	2009	1.42 – 1.98

Notes:

[(a)]Alternative 3 was assessed in the 2021 Lake Analysis and assumed that of the total Replenish Big Bear effluent contribution considered in the Lake Analysis (i.e., 2,000 AFY), 80 AFY would be delivered to Shay Pond. Therefore, only 1,920 AFY would be discharged to the Lake.

[(b)]The updated model analysis assumed that no discharge to Shay Pond would occur and all recycled water would be discharged to the Lake under two different total recovery rates scenarios.

Moreover, deliveries are expected to vary seasonally (Fig 1), thus varying from the earlier "Alternative 3" scenario that assumed uniform flows of 1.71 MGD throughout the year. Inflows to the WWTP are lower in the summer months due to reduced inflow.

Since the Replenish Big Bear project does not have a waste load allocation for total P (TP) in the current TMDL, it is proposing to offset the TP load in the project inflows delivered to Big Bear Lake. While RO is extremely effective at removing dissolved and particulate substances, there nonetheless is a small quantity of TP that is expected to evade treatment (the projected RO effluent concentration is 0.03 mg/L, principally as o-PO_4-P). Elimination of all TP through the treatment process is not practicable, so removal of an equivalent load of TP (up to 200 lbs/yr) from elsewhere in the lake or watershed will be necessary.

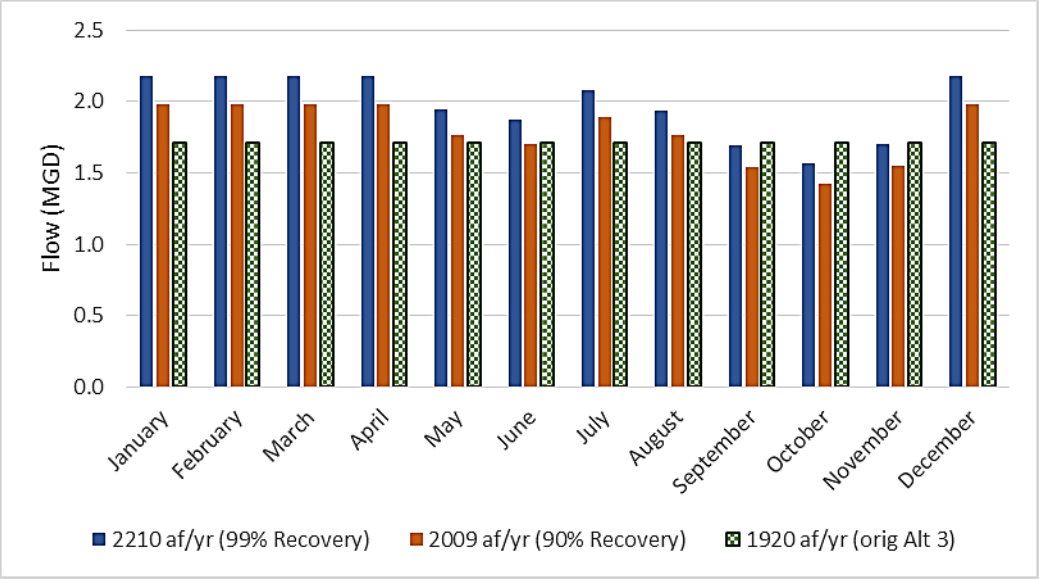

Fig. 1. Monthly flow rates (projected 2040) for Replenish Big Bear under three project inflow scenarios.

In light of these factors, further modeling was conducted to evaluate predicted water quality under these operational scenarios (increased and time-varying flows, with and without TP offset) for comparison with the previously predicted baseline condition and Alternative 3 scenario. Given the complexity of nutrient budgets of lakes, array of possible offset strategies, and equivalence of a given form of nutrient irrespective of its particular origin, TP offset will be modeled as equivalent to 0 influent concentration. This is an approximation that holds when considering whole-lake nutrient budget, but is nonetheless a simplification; depending upon details of offset, hydrodynamic considerations and other factors, some modest lateral gradients in water quality may result. The 50th percentile hydrologic scenario for 2009-2050 was used in this analysis, noting that it includes a wide array of runoff conditions, included extended drought and as well as periods of high runoff. All other hydrologic, meteorological, biological, chemical and sedimentological factors, variables and conditions were identical to those used in prior simulations of long-term future conditions (Anderson, 2021).

Results

Long-term averaged predicted concentrations of TDS, TIN, total P, total N and chlorophyll-a were lower with addition of RBB water compared with predicted baseline conditions (no supplementation) (Table 2). For reference, TMDL target values are included in the table. Focusing on chlorophyll-a as the key response target, baseline conditions were predicted to yield growing-season average chlorophyll-a concentration that slightly exceeded (by 0.1 µg/L) the TMDL target value of 14 µg/L, while Alternative 3 matched the target value, and larger inputs of RBB inflow that varied seasonally (Fig. 1) yielded values below baseline and TMDL target values (Table 2). Zeroing out the load of TP in RBB inflow yielded further reductions in chlorophyll-a; larger inflow volumes with reduced summer flows and no net TP loading were predicted to yield growing season average chlorophyll-a concentrations as low as 9.5 - 10.2 µg/L, significantly below predicted baseline and TMDL concentrations (Table 2).

Table 2. Long-term average predicted concentrations of total P, total N and chlorophyll-a in Big Bear Lake under different operational scenarios (total P and total N expressed as annual average concentrations; chlorophyll-a shown as growing season average concentrations).

Operational Scenario (all at 50th % hydrology)	**TDS (mg/L)**	**TIN (mg/L**	**Total P (µg/L)**	**Total N (mg/L)**	**Chlorophyll-a (µg/L)**
Baseline	**195**	**0.069**	**47.7**	**1.15**	**14.1**
Alternative 3 (1920 af)	182	0.052	43.3	1.07	14.0
2210 af (99% recovery)	**179**	**0.045**	**42.3**	**1.04**	**13.1**
2009 af (90% recovery)	**180**	**0.041**	**43.4**	**1.06**	**12.9**
2210 af + 0 total P	179	0.072	39.9	1.00	10.2
2009 af + 0 total P	180	0.040	40.9	1.00	9.5
TMDL target			***35.0***		***14.0***

Supplementation with RBB inflow also lowered concentrations of total P and total N relative to predicted baseline levels (Table 2). This is consistent with the reduced concentrations of total N and total P (and most dissolved forms of N and P) in RO water relative to watershed runoff concentrations (Anderson, 2021, Table 20), with concentrations projected to be only 40% - 80% of average watershed runoff concentrations (Anderson, 2021, Table 21). Interestingly, zeroing out the influent TP concentration not only lowered the predicted average total P concentration but also reduced the predicted total N concentrations, highlighting the complex biogeochemical coupling of these two key nutrients. While it is important to recognize the uncertainty in model predictions, it is nonetheless noteworthy that revised project flows, with varying seasonal flow and TP offset, yielded average chlorophyll-a concentrations significantly below baseline and TMDL values and also yielded long-term average TN concentrations approaching or reaching 1 mg/L, which is being considered by the Regional Water Board. Predicted long-term average TP concentrations remained above the TMDL target, but were nonetheless meaningfully lower than the predicted baseline level (Table 2). Average TDS and TIN concentrations were also lower than predicted baseline conditions (with exception of 2210 af + 0 TP, where a period of higher NO_3-N was predicted).

Inter-annual differences in water quality are nonetheless expected to persist. Cumulative distributions functions (CDFs) highlight the predicted wide range in annual and growing season average concentrations (Fig. 2). While addition of RBB inflow shifted CDFs to lower annual average total P and total N concentrations and growing season average chlorophyll-a concentrations, wide ranges in predicted concentrations remained in place (Fig. 2). Thus, the growing season average chlorophyll-a target of 14 µg/L was predicted to be exceeded about 53% of the time under baseline conditions, and exceeded about 41% and 31% of the time with RBB inflows of 2210 af/yr without and with TP offset, respectively (Fig. 2c; Table 3). Results for all scenarios are summarized in Table 3.

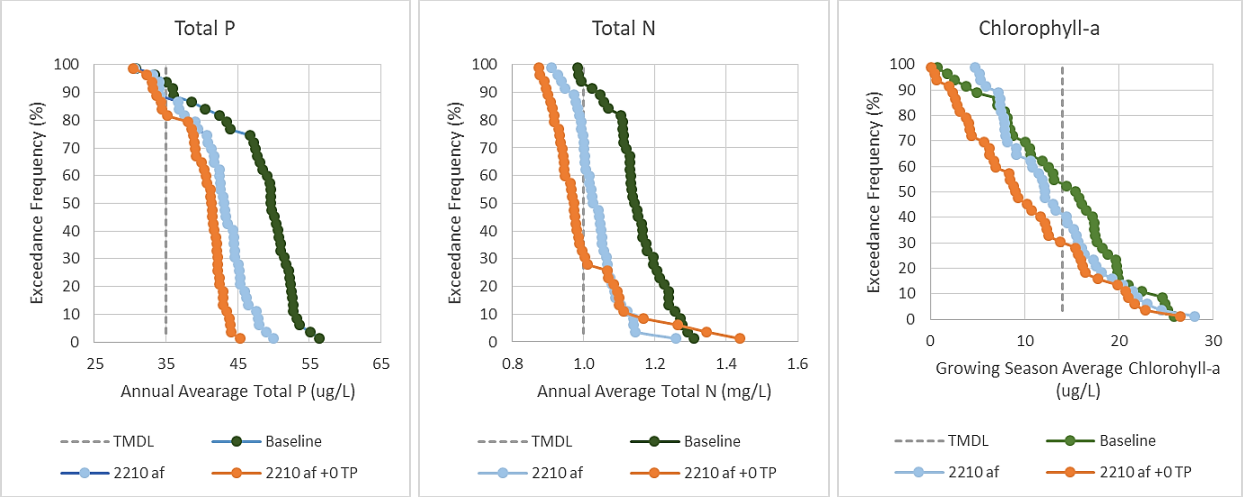

Fig. 2. Cumulative distribution functions for predicted annual total P and total N concentrations and growing season average chlorophyll-a concentrations for baseline condition and with 2210 af RBB inflow with and without TP offset.

Table 3. Predicted frequency of exceeding TMDL target under baseline conditions and different RBB inflow and TP offset scenarios (annual average or growing season average basis). Observed annual exceedance frequencies for 2009-19 period shown in parentheses under Baseline.

Variable	**Baseline**	**1920 af**	**2210 af**	**2210 af+0 TP**	**2009 af**	**2009 af+0 TP**
Total P	94 % (100%)	87 %	87 %	82 %	91 %	90 %
Total N[a]	91 % (na)	72 %	72 %	30 %	80 %	55 %

APPENDIX E: BIG BEAR LAKE AMMONIA AND HARDNESS CALCULATIONS

Constituent: Ammonia as N

Nutrient TMDL Data

For this analysis, the lake-wide annual average was estimated by averaging the four station annual averages consistent with the Nutrient TMDL approach, which consist of averaging the photic and bottom samples for each sampling date.

	Station 1	Station 2	Station 6	Station 9	Lake Wide Annual Average
Min	0.015	0.010	0.010	0.010	0.013
Max	0.306	0.230	0.245	0.135	0.167

Constituent: Hardness as CaCO3

Appendix E - Big Bear Lake Ammonia and Hardness Calculations

Nutrient TMDL Data

For this analysis, the lake-wide annual average was estimated by averaging the four station annual averages consistent with the Nutrient TMDL approach, which consist of averaging the photic and bottom samples for each sampling date.

	Station 1	Station 2	Station 6	Station 9	Lake Wide Annual Average
Min	124	126	127	131	128
Max	200	193	193	200	191
Average	161	161	164	164	163
Median	160	163	165	164	163

APPENDIX F: BORON MASS BALANCE ANALYSIS WITH LAKE DISCHARGE

Due to the limited amount of water quality data available, a simple spreadsheet model was completed to evaluate the contribution of the Lake discharge to boron concentrations in the Lake over time. See Section 5.3.2 of the Antidegradation Analysis for equations used.

Year	Lake Storage (AF)		Inflows (AF)		Outflows			Boron (mg/L)			Mass boron (pounds)				Lake at End		
Year	Watermaster	Adjusted Storage	Natural Inflows	BBARWA Discharge	Evaporation	Releases + Withdrawals + Leakage	Additional Releases	Lake	Inflow	Discharge	Lake	Inflow	Discharge	Releases	Mass	Volume (AF)	Concentration (mg/L)

1 Introduction

This study assesses the groundwater quality beneath Big Bear Area Regional Wastewater Agency's (BBARWA's) Lucerne Valley Land Discharge Location (LVLDL) in Lucerne Valley in San Bernardino County, California (see Figure 1). The LVLDL consists of a 480-acre property of which 190 acres is used to grow various animal feed crops. Beginning in 1980, BBARWA has discharged all of their treated wastewater to the LVLDL, which is primarily used to irrigate the crops, although some of the water is periodically discharged to two unlined basins located on the southern end of the property (see Figure 2). This report has been prepared to assess changes in groundwater quality beneath the LVLDL area since BBARWA began collecting groundwater quality data in 1991.

1.1 Background

BBARWA has been discharging treated recycled water at the LVLDL since 1980. Treated water is conveyed via a pipeline from the BBARWA treatment plant near Big Bear City to the LVLDL located approximately 12 miles to the north (see Figure 1). The delivered water is discharged first to a lined balancing reservoir, located approximately 6,500 ft south of the LVLDL, and then distributed to irrigate crops. Crops grown on the LVLDL typically include alfalfa, fiber and seed crops. During periods of low crop water demand and/or high discharges, some of the water is discharged to two unlined basins on the south end of the property (see Figure 2).

Since 1991, recycled water discharges have been regulated under California Colorado River Regional Water Quality Control Board's (RWQCB's) Order No. 01-156. On June 30, 2016, the RWQCB adopted revised Waste Discharge Requirements (WDRs) for BBARWA in Order R7-2016-0026 (see Appendix A). As part of this new order, the RWQCB is requiring preparation of a study to assess the impacts that historical recycled water discharges have had on groundwater quality beneath the LVLDL (Order R7-2016-0026; Section E, No. 1).

The primary constituents of concern (COCs) of this study are total dissolved solids (TDS) and nitrate (as N). The maximum contaminant levels (MCLs) for TDS and nitrate (as N) are 500 and 10 milligrams per liter (mg/L), respectively. The RWQCB Basin Plan Objective for TDS and nitrate is to maintain the water quality to existing historical conditions where possible and to keep the chemical and physical groundwater quality close to or otherwise below the MCLs (RWQCB, 2006). Specific concentration limits for TDS and nitrate have not been established.

1.2 Site Description

The LVLDL (the Site) consists of approximately 480 acres of mostly cultivated land in Lucerne Valley in San Bernardino County, California (see Figures 1 and 2). The LVLDL is located

southeast of the intersection of Old Woman Springs Road and Camp Rock Road. Crops grown on the LVLDL typically include alfalfa, fiber and seed crops. During periods of low crop water demand and/or high discharges, some of the water conveyed to the LVLDL from BBARWA is discharged to two unlined basins on the south end of the property (see Figure 2).

There are three monitoring wells (MW-1, MW-2, and MW-3) located within the LVLDL. MW-1 is located on the south end of the property and MW-2 and MW-3 are located on the north end (see Figure 2). Groundwater levels and groundwater quality data have been collected from the monitoring wells on a semi-annual to annual basis since they were completed in 1991. Each monitoring well is constructed of 4-inch diameter polyvinyl chloride (PVC) casing to a depth of 250 feet below ground surface (ft bgs). The wells are each constructed with multiple perforation intervals between 135 ft bgs and 250 ft bgs (see Appendix B). The monitoring wells are completed 2.5 ft above ground surface with locking monument casing.

The land use surrounding the LVLDL is predominantly native, undisturbed vegetation with sporadic homes. There are approximately eleven homes in the vicinity of the site, four of which are upgradient of the site (see Figure 4). The homes in this area all discharge their wastewater via individual onsite septic tanks.

1.3 Purpose and Scope

The purpose of this report is to summarize an analysis of historical groundwater quality beneath the LVLDL in the context of historical BBARWA discharges and land use on and surrounding the site.

The report includes:

- An assessment, based on historical records, of ambient (pre-BBARWA discharges) groundwater nitrate and total dissolved solid (TDS) concentrations in the vicinity of the LVLDL;
- Documentation and analysis of historical nitrate and TDS concentrations in recycled water discharges;
- Documentation and analysis of historical trends in nitrate and TDS concentrations in groundwater collected from onsite monitoring wells;
- Analysis of historical groundwater level changes at the LVLDL;
- Analysis of groundwater flow direction and gradient in the vicinity of the LVLDL; and
- An analysis of potential sources of nitrate and TDS in groundwater other than BBARWA recycled water, including, but not limited to, onsite farming practices and potential up gradient sources.

2 Sources of Data

The evaluation of TDS and nitrate concentrations in groundwater beneath the LVLDL is based on existing data, reports, and maps. Since 1991, BBARWA has historically collected groundwater level and groundwater quality data from monitoring wells MW-1 through MW-3 on a semi-annual to annual basis. Groundwater quality constituents analyzed have typically included general minerals, such as TDS, nitrate, etc., and physical properties.

The following sources of data were utilized in the analysis:

- BBARWA
  - Historical monthly wastewater discharge volumes from the BBARWA treatment plant
  - Historical TDS and total inorganic nitrogen (TIN) concentrations in effluent from the BBARWA treatment plant
  - Nitrate and TDS concentrations in groundwater samples collected from MW-1, MW-2, and MW-3
  - Historical groundwater levels measured in MW-1, MW-2, and MW-3
  - Annual total discharges to the unlined ponds (basins) at the LVLDL
  - Annual total discharges to the fields at the LVLDL

The period of record for this analysis is from 1991 through 2016.

3 Description of the Site

3.1 Geology

3.1.1 Regional Geologic Setting

The Lucerne Valley is located on the northern slope of the San Bernardino Mountains (CDWR, 2003; see Figure 1) within the northwestern portion of the Colorado River Basin. The basin formed during the uplift of the San Bernardino mountain range (USGS, 2000). The east-west trending valley is bounded by the Ord Mountains to the north, the Fry Mountains to the east, the San Bernardino Mountains on the south, and the Granite Mountains to the west (Pioneer Consultants, 1977). The most prominent geologic fault in the area is the Helendale Fault, a north-west trending, right lateral, strike-slip fault located southwest of the LVLDL (see Figure 1; Pioneer Consultants, 1977).

3.1.2 Geologic Units

The surrounding and underlying bedrock consists of pre-Tertiary igneous and metamorphic rock (Pioneer Consultants, 1977). Surficial sediments that make up the interior of the basin consist of Quaternary age alluvial fan, washes, and landslides (USGS, 2000). The alluvial fan deposits consist of unconsolidated to semi-consolidated sand, gravel and cobbles. The lowest elevation of the closed basin is the Lucerne Dry Lake, where sediments consist of lacustrine silt and clay deposits.

Borehole logs from the monitoring wells at the LVLDL state that the subsurface is primarily composed of sand and gravel with some minor interbedded silty and clayey sand to a depth of approximately 255 ft bgs (Law Environmental, Inc., 1992).

3.2 Hydrogeology

3.2.1 Regional Hydrogeology

The LVLDL is located within the Lucerne Valley Groundwater Basin (the Basin), as defined by CDWR's Bulletin 118 (CDWR, 2003). Topographically, the Basin is a closed hydrologic system such that all surface water flow terminates within the Basin at Lucerne Dry Lake (see Figure 1). Groundwater flow out of the basin is also assumed to be negligible (Pioneer Consultants, 1977).

The aquifer in the Basin is recharged from precipitation runoff and infiltration along the base of the San Bernardino Mountains and, to a lesser degree, along the Ord and Fry Mountains to the north (Pioneer Consultants, 1977; DWR, 1975). The primary source of groundwater discharge is through evapotranspiration at Lucerne Dry Lake. Previous reports have indicated that the aquifer in the vicinity of the LVLDL is unconfined (Blazevic, et al., 2005).

3.2.2 Local Groundwater Occurrence and Flow

Based on hydrographs from MW-1 through MW-3, groundwater elevations are generally between 2,845 and 2,885 ft above mean sea level (ft amsl; see Figure 3 and Table 1). This corresponds to a groundwater level depth of approximately 125 to 175 ft below ground surface (ft bgs). Groundwater elevations in MW-1 (the upgradient well) are generally 25 ft higher than those in MW-2 and MW-3. Since the onsite groundwater monitoring wells were first constructed in 1991, groundwater levels beneath the LVLDL have generally been rising (see Figure 3). Although there is year-to-year variation associated with precipitation trends, groundwater levels have risen approximately 10 ft beneath the Site between 1991 and 2016.

The groundwater flow direction beneath the LVLDL is generally to the northwest (see Figure 4). Although the groundwater elevations have changed over time as seen on Figure 3, the groundwater flow direction has been consistently towards the Lucerne Dry Lake.

3.2.3 Groundwater Quality

The native groundwater quality within the Lucerne Valley Groundwater Basin varies greatly with respect to location in the Basin. In the southern upgradient portion of the Basin, TDS concentrations in groundwater are generally below 500 mg/L. In the downgradient portion near Lucerne Dry Lake, natural TDS concentrations in groundwater increase significantly as a result of evaporative concentration. Time series plots of TDS concentration for the period between 1952 and 1980 for two wells immediately north of the Site (04N01E06H01S and 05N01E32R01S) show that TDS concentrations before 1980 (prior to BBARWA's discharge operation) were generally between 350 and 500 mg/L but periodically spiked above 500 mg/L (Schlumberger, 2007). The cause of the TDS spikes is unknown, but may be associated with localized pumping depressions that reverse the groundwater flow gradient, resulting in the capture of high TDS groundwater from beneath Lucerne Dry Lake, which is known to have TDS concentrations ranging from 2,000 to 3,000 mg/L (Schlumberger, 2007). The average TDS concentration in the Lucerne Valley Groundwater Basin is reported to be approximately 1,100 mg/L, although the average concentration in the southern portion of the Basin (south of Old Woman Springs Road and including the LVLDL) is likely closer to 500 mg/L.

Data regarding nitrate concentrations in groundwater in the vicinity of the LVLDL was not available for the period prior to 1980 when the facility began operation. The earliest available data, from 1991 through 1998, show nitrate concentrations in groundwater in the Lucerne Valley to be less than 2 mg/L (SWRCB, 2017).

3.3 BBARWA Operations

Treated wastewater from BBARWA's treatment plant near Big Bear City is conveyed to the LVLDL via a pipeline (see Figure 1). The pipeline follows State Highway 18 until Camp Rock

Road, at which time it trends due north to the Site. Between 2000 and 2016, the average monthly discharge to the site was 70 million gallons per month. The average annual flow to the Site for the same time period is approximately 2,580 acre-ft/yr.

Treated water delivered to the LVLDL is either conveyed to an irrigation system for application on crops or discharged to two unlined basins located on the south end of the property. On an annual basis, the volume of water used for irrigating crops is typically approximately two thirds of the water discharged to the basins (see Figure 5). On a monthly basis, the percentage of delivered water discharged to crops is highest during the growing season (March through October) while the opposite is true between November and February (see Figure 6).

4 Analysis of Groundwater Quality Changes at the Lucerne Valley Land Discharge Location

4.1 BBARWA Water Quality

The quality of the water delivered to the LVLDL is addressed herein as it relates to TDS and Nitrate concentrations. The TDS concentration of the water delivered to the LVLDL, based on monthly averages measured at the BBARWA treatment plant, ranges from 318 mg/L to 519 mg/L (see Figure 7). The TDS concentration in the treated water has remained below 500 mg/L except for two months in 2014. Except for periodic outliers, the TDS concentration in the delivered water is typically between 400 and 500 mg/L.

Nitrate (as N) concentrations in the water delivered to the LVLDL from BBARWA have changed over time as a result of nitrate treatment at the BBARWA plant. Between 1990 and 1997, nitrate concentrations in the delivered water were highly variable and ranged from none detected to greater than 20 mg/L (see Figure 8). As the MCL for nitrate is 10 mg/L, BBARWA implemented a nitrate treatment process, which became operational in 1997. Since 1997, nitrate concentrations in the water delivered to the LVLDL have ranged from none detected to 13 mg/L but are typically below the MCL of 10 mg/L (see Figure 8).

4.2 Groundwater Quality

4.2.1 TDS Concentrations in Groundwater

The lowest TDS concentrations detected in groundwater samples collected from the three monitoring wells in the LVLDL area have been from the upgradient well (MW-1). Prior to 2010, the TDS concentration in MW-1 was relatively stable at approximately 300 mg/L (see Figure 7). As this concentration is from the upgradient well, it is likely indicative of the native TDS concentration of the aquifer beneath the Site prior to discharges at the LVLDL. Since 2010, the TDS concentration in samples from MW-1 has steadily increased and has periodically spiked as high as 720 mg/L (see Table 2). The reason for this increase is unknown but, given the well's location on the upgradient portion of the Site, it is likely associated with an upgradient TDS source.

TDS concentrations in samples from the two downgradient monitoring wells at the LVLDL (MW-2 and MW-3) show relatively stable trends between 2000 and 2010 and decreasing trends since 2010. Since 2000, TDS concentrations in these wells have ranged from approximately 500 mg/L to 900 mg/L and more recently the concentrations have been between 500 mg/L and 700 mg/L. It is noted that the TDS concentration detected in MW-2 rose sharply between construction of the well in 1991 and 1998. Concentrations rose as high as 1,200 mg/L before declining again and eventually becoming stable between approximately 700 and 800 mg/L after 2001 (see Figure 7). The reason for this spike in concentration is not clear, as

samples collected and analyzed from the nearby downgradient monitoring well (MW-3) did not show the same TDS concentration or trend. As MW-2 is directly downgradient of an irrigated field, the concentrations may be associated with the leaching of accumulated salts into the groundwater beneath the agricultural fields. This could have occurred during the period of high precipitation preceding 1998 or as a result of irrigation practices.

Prior to the start of BBARWA's discharges to the LVLDL in 1980, TDS concentrations in groundwater to the north and downgradient of the site were known to be relatively high. Time series plots of TDS concentration for the period from 1952 to 1980 for two wells approximately three miles northwest of the Site (04N01E06H01S and 05N01E32R01S; see Figure 2) show that TDS concentrations before 1980 were generally between 350 and 500 mg/L but periodically spiked as high as 1,500 mg/L (Schlumberger, 2007). TDS concentrations further north in the vicinity of Lucerne Dry Lake have been higher, at concentrations greater than 4,000 mg/L. The average TDS concentration in the Lucerne Valley Groundwater Basin is 1,099 mg/L (Schlumberger, 2007). Potential sources of high TDS groundwater northwest and downgradient of the LVLDL may include historical farming operations and evaporative concentration of salts beneath the dry lake. As the downgradient TDS concentrations are equal to or above the TDS concentrations of water delivered to the LVLDL from BBARWA, the current discharges are not predicted to degrade existing groundwater quality or limit existing beneficial uses.

4.2.2 Nitrate Concentrations in Groundwater

Nitrate concentration changes in groundwater samples collected from the upgradient monitoring well MW-1 between 1991 and 2016 are likely associated with historical discharges at the LVLDL basins or an upgradient source(s). The nitrate concentration in the sample collected in 1991 was 4.8 mg/L (see Figure 8). Concentrations in samples from this well rose to 10.5 mg/L (just over the MCL of 10 mg/L) between 1991 and 2000, decreased to between 7 and 8 mg/L between 2004 and 2010, and then started increasing again to as high as 15.7 mg/L in 2015. The initial rise in concentrations between 1991 and 2000 was likely associated with the higher concentration of nitrate in the delivered water that was discharged to the unlined basins between 1991 and 1997. With the delivery of treated water with lower nitrate concentrations in 1997, the nitrate concentration in MW-1 dropped between 2000 and 2010. Since 2010, nitrate concentrations in samples from MW-1 have been increasing, despite the fact that nitrate concentrations in the delivered water remain, for the most part, lower than the concentrations in MW-1. This trend is similar to that observed for TDS and suggests that there is an upgradient source of the nitrate and TDS that is contributing to the concentrations observed in this well.

Nitrate concentration changes in groundwater samples collected from the downgradient monitoring wells MW-2 and MW-3 between 1991 and 2016 are likely associated with irrigation practices and agricultural land use at the LVLDL. Nitrate concentrations between 2000 and 2016 generally range from 14 to 20 mg/L and show a decreasing concentration trend over time

(see Figure 8; Table 2). The decreasing concentrations may be a result of lower concentrations in the delivered BBARWA water, increased irrigation efficiency, or both. The nitrate spike observed in the samples from MW-2 collected between 1997 and 2000 correlate with a similar spike in TDS concentrations observed in the samples from this well during the same time. Nitrate concentrations were detected as high as 70 mg/L during this time. As MW-2 is directly downgradient of an irrigated field, the concentrations may be associated with differential fertilization and/or overirrigation of the crops directly upgradient of this well during this time, cross-contamination during sampling, or some other source. It is noted that WSC (2016) conducted a study of the nitrate demand and historical fertilization practices for the crops grown at the LVLDL and found that there was no evidence of over-fertilization of the fields.

4.2.3 Analysis of Changes in Groundwater Quality at the LVLDL

The TDS and nitrate concentrations in groundwater directly beneath the LVLDL between 1991 and 2016 appear to be associated with a combination of native groundwater quality, delivered BBARWA water quality, agricultural land use, and upgradient sources. Data from the upgradient well MW-1 suggests that the native TDS beneath the Site was approximately 300 mg/L. The TDS of treated water delivered to the Site from BBARWA has ranged from 400 to 500 mg/L. Although the BBARWA delivered water could account for somewhat higher TDS concentrations in groundwater beneath the site (between 300 and 500 mg/L), even higher concentrations detected in the downgradient monitoring wells (MW-2 and MW-3), which range from 500 to 900 mg/L, appear to be associated with a source other than BBARWA treated water delivered to the site. The same correlation is also true of nitrate for the time period between approximately 2000 and 2016.

The most likely source of the elevated TDS and nitrate concentrations in the groundwater at the downgradient wells is historical return flow from irrigation and fertilization in excess of plant demands. Based on interviews of the farmers of the crops on the LVLDL, as reported in BBARWA's Draft Irrigation Management Plan for the Lucerne Valley Facility (WSC, 2016), the rate of fertilizer application does not exceed the crop demand. As such, it is possible that irrigation practices, such as periodic overwatering, could have leached the nitrogen below the root zones of the plants and into the groundwater before the plants were able to absorb the fertilizer.

Since 2010, increases in TDS and nitrate concentrations in the upgradient monitoring well (MW-1) are likely associated with an upgradient source. There are multiple homes in the vicinity of the LVLDL (see Figure 4). Homes in this area discharge their wastewater through individual onsite septic systems. There are three homes upgradient of the LVLDL and one home is located approximately 1,400 feet upgradient from MW-1. Given that the TDS and nitrate concentrations detected in samples from MW-1 since 2010 generally exceed concentrations in

the delivered water from BBARWA and, in some cases, the concentrations in the downgradient monitoring wells, an upgradient source is likely and discharges via individual septic systems are a plausible source.

Changes in groundwater quality over time from 1991, 1998 and 2001 in wells MW-1 through MW-3 are shown on Figure 9 in the form of a trilinear or piper diagram. A piper diagram presents selected major constituents, including calcium, magnesium, sodium, potassium, bicarbonate, chloride and sulfate and graphically illustrates the results of the water quality analysis. As shown, the general water chemical signature of samples collected from the upgradient well is distinct from the water chemical signature of the samples from the downgradient wells. As the most recent samples were collected in 2001, this likely illustrates the difference between the native water quality and the water quality changes associated with agricultural land use. Changes in the upgradient MW-1 water quality between 1991 and 2001 may be associated with influence from the infiltration of delivered BBARWA water in the unlined basins and/or upgradient sources.

5 Conclusions and Recommendations

Based on the findings of this study, TH&Co has developed the following conclusions:

- Groundwater levels in monitoring wells at the Site have risen steadily since the wells were constructed in 1991 (see Figure 3) and indicate that natural recharge to the aquifer beneath the Site is being supplemented from a combination of irrigation return flow and discharge to the unlined basins.
- With the exception of periodic spikes, TDS and nitrate concentrations in the water delivered to the LVLDL are generally below the secondary MCL for TDS (500 mg/L) and primary MCL for nitrate (10 mg/L). The average TDS concentration in the BBARWA water is 427 mg/L from 1991 to 2015 and the average nitrate concentration from 2002 to 2017 is 2.4 mg/L.
- As the TDS and nitrate concentrations in the delivered water from BBARWA are lower than the TDS and nitrate concentrations detected in samples from the downgradient monitoring wells at the Site (MW-2 and MW-3), it is concluded that the delivered water from BBARWA is not the source of the high TDS and nitrate concentrations in these two wells.
- A possible source of high TDS and nitrate concentrations in groundwater from MW-2 and MW-3 is the leaching of salts and fertilizer in return flow from the agricultural operation.
- Historical TDS concentrations in groundwater downgradient of the LVLDL have been equal to or higher than the TDS concentrations in BBARWA's water delivered to the LVLDL. The downgradient high TDS concentrations were measured prior to BBARWA's discharge at the site and may be related to other farming operations in the area and, to a lesser degree, capture of high TDS groundwater resulting from evaporative concentration of salts beneath Lucerne Dry Lake.
- Recent increases in TDS and nitrate concentrations in the upgradient monitoring well at the Site (MW-1) indicate that an upgradient source is contributing to the elevated TDS and nitrate concentrations in the groundwater beneath the Site. A potential offsite source of the high TDS and high nitrate may be discharges from one or more individual septic systems at homes located upgradient of the Site.

The RWQCB does not currently have a Basin Plan Objective for TDS in groundwater in the Lucerne Valley Groundwater Basin. The secondary MCL for TDS in groundwater is 500 mg/L. Prior to BBARWA's discharges to the LVLDL in 1980, TDS concentrations in wells downgradient of the Site generally ranged from approximately 350 to 500 mg/L but periodically spiked as high as 1,500 mg/L. In the furthest downgradient portion of the Basin beneath Lucerne Dry Lake, the TDS concentrations in groundwater are significantly higher. The average TDS concentration in the Basin as a whole is approximately 1,100 mg/L (Schlumberger, 2007).

As the downgradient TDS concentrations in groundwater are equal to or above the TDS concentrations of water delivered to the LVLDL from BBARWA and the basinwide average TDS concentration is above that of the delivered water, the delivered water is not predicted to degrade the existing groundwater quality or limit existing downgradient beneficial uses. The previous BBARWA effluent limit for TDS is 400 mg/L over the TDS of the domestic source water. Based on the findings of this groundwater quality evaluation, there is no need to change BBARWA's discharge TDS limit from the existing criteria.

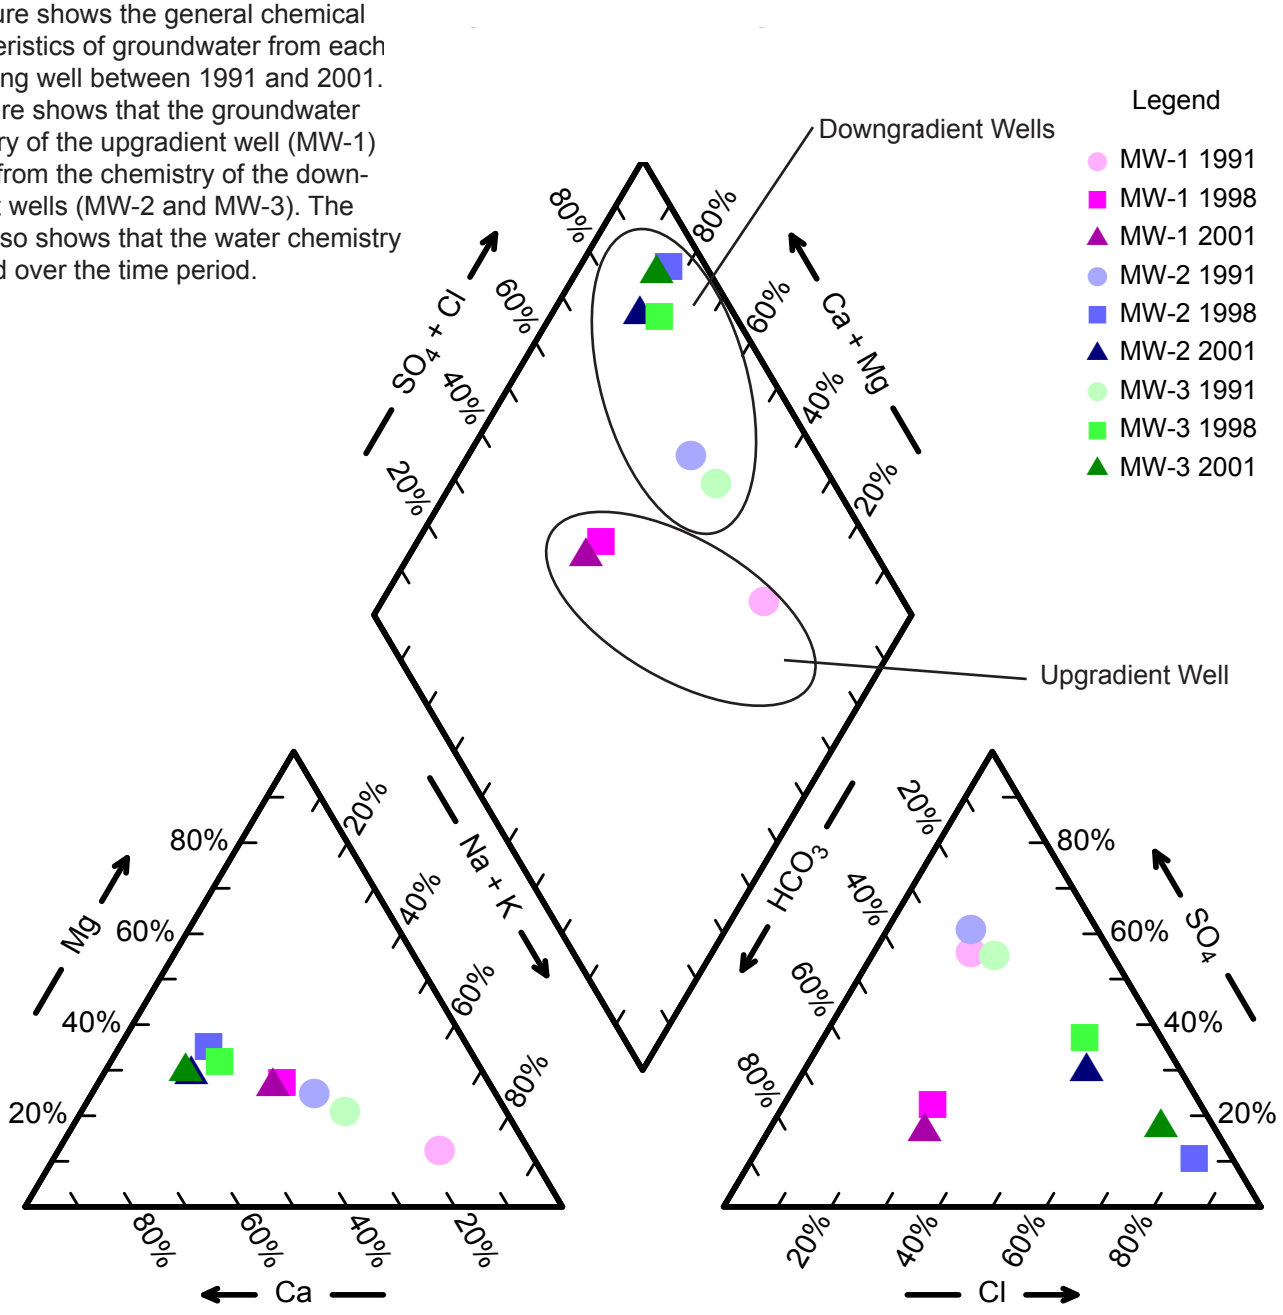
Figure 9

Monitoring Wells Piper Diagram

This figure shows the general chemical characteristics of groundwater from each monitoring well between 1991 and 2001. The figure shows that the groundwater chemistry of the upgradient well (MW-1) distinct from the chemistry of the down-gradient wells (MW-2 and MW-3). The figure also shows that the water chemistry changed over the time period.



Appendix A

RWQCB's Investigative Order No. R7 to 2016 to 0026

CALIFORNIA REGIONAL WATER QUALITY CONTROL BOARD
COLORADO RIVER BASIN REGION

BOARD ORDER R7-2016-0026

WASTE DISCHARGE REQUIREMENTS
FOR
BIG BEAR AREA REGIONAL WASTEWATER AGENCY, OWNER/OPERATOR
EXPORT OF RECYCLED WATER TO LUCERNE VALLEY
Lucerne Valley – San Bernardino County

The California Regional Water Quality Control Board, Colorado River Basin Region (Colorado River Basin Water Board) finds that:

1. Big Bear Area Regional Wastewater Agency (BBARWA or Discharger), P. O. Box 517, Big Bear City, California 92314, owns 480 acres in the Lucerne Valley, of which 340 acres are irrigated with recycled water from the Discharger's Wastewater Treatment Plant (WWTP). There are an additional 140 acres available for irrigation, also in the Lucerne Valley. BBARWA's WWTP provides sewerage service to the City of Big Bear Lake, Big Bear City Community Services District, and County Service Area 53-B. The WWTP is located at 122 Palomino Drive, Big Bear City, California 92314, and has a design treatment capacity of 4.89 million gallons-per-day (MGD) and a hydraulic capacity of 9.2 MGD.

2. The WWTP is located outside the boundary of the Colorado River Basin Water Board and is regulated by the California Regional Water Quality Control Board, Santa Ana Region (Santa Ana Water Board) under Waste Discharge Requirements (WDRs) Order R8-2005-0044.

3. The WWTP consists of: preliminary treatment, secondary treatment, and sludge drying and treatment. Secondary treated wastewater from the WWTP is disposed through three possible discharge points that are designated in Board Order R8-2005-0044 as Point 001, Point 002 and Point 003. The discharges from the WWTP at Points 002 and 003 are regulated by the Santa Ana Water Board. Most of the treated wastewater is discharged through Discharge Point 001 into the Lucerne Valley to irrigate fodder, fiber, and seed crops.

4. This Board Order regulates the discharge from the WWTP at Point 001. Infrastructure associated with this discharge includes a concrete-lined reservoir and two overflow ponds that are used to dispose of treated recycled wastewater by percolation and evaporation in the Lucerne Valley (Lucerne Valley Facility) located on Assessor's Parcel Number (APN) 0449-082-040000.

5. The Lucerne Valley Facility has been subject to WDRs adopted in Colorado River Basin Water Board Order 01-156 adopted November 14, 2001.

6. The WDRs are being updated to comply with current laws and regulations as set forth in the California Water Code (CWC) and the California Code of Regulations (CCR) and to incorporate any changes in ownership or operation undertaken by the Discharger.

7. The Lucerne Valley Facility is assigned California Integrated Water Quality System (CIWQS) number CW- CW-208930; Waste Discharger Identification (WDID) number 7A360100011, and GeoTracker Global ID number WDR100027897.

Wastewater Treatment and Discharge

8. The Lucerne Valley Facility is located on 480 acres owned by BBARWA and located near the intersection of State Hwy 247 (Old Woman Springs Road) and Camp Rock Road in the Lucerne Valley of San Bernardino County in Section 14, Township 4 North, Range 1 East, San Bernardino Base & Meridian, as shown in Attachment A, Vicinity Map, incorporated herein, and made part of this Board Order by reference.

9. Wastewater that is discharged at the Lucerne Valley Facility goes through preliminary and secondary treatment at the WWTP before it is sent via gravity to the concrete reservoir at the Lucerne Valley Facility. The WWTP components that are used for treatment are described below:

   a. Preliminary Treatment. Untreated wastewater flows to the preliminary treatment system, which consists of bar screens, aerated grit chamber with grit washer, and a flow bypass channel. This treatment stage removes screenings, rag material and grit.

   b. Secondary Treatment. Effluent flows by gravity from the preliminary treatment system to three parallel oxidation ditches for secondary (biological) treatment and timed processes for nutrient (nitrogen) removal. The number of ditches in operation depends on the seasonal fluctuations of the influent flow. The effluent from the oxidation ditches flows into a system of three secondary clarifiers for removal of floatable and settleable solids/materials. The secondary treated effluent flows to two cement-lined balancing chambers and then flows to equalization storage ponds at the WWTP until pumped for offsite irrigation disposal. A process flow diagram of the WWTP is shown on Attachment B, incorporated herein, and made part of this Board Order by reference.

   c. Offsite Irrigation/Disposal. Undisinfected secondary treated wastewater is pumped from the WWTP's main pump building (5.2 MGD) or auxiliary pump building (9.2 MGD) approximately 16.5 miles to an offsite 2.26-million gallon concrete-lined reservoir (undisinfected secondary recycled water reservoir). This reservoir is located one mile south of the irrigation site. Wastewater from the reservoir flows by gravity through an outfall line connected to the irrigation system. In the event of an overflow at the concrete-lined reservoir, the wastewater flows by gravity to earthen overflow ponds located adjacent to the irrigation site.

10. Approximately 2.01 MGD of undisinfected secondary recycled water (as defined in Title 22 California Code of Regulations Section 60301.900) is discharged to the Lucerne Valley Facility for irrigation of fodder and fiber crops. Undisinfected secondary wastewater has been approved by the California Department of Public Health (DPH) [now State Water Resources Control Board (SWRCB) Division of Drinking Water (DDW)] for irrigation use at this site. Approximately 340 acres are being irrigated at the Lucerne Valley Facility, with an additional 140 acres available for irrigation at the site. The effluent discharge limit of 4.8 MGD in this Board Order is based on the capacity of the irrigated crops to take up nitrogen. The Lucerne Valley Facility site layout is shown in Attachment C, incorporated herein, and made part of this Board Order by reference.

11. The SWRCB's Division of Drinking Water has established statewide reclamation criteria in Title 22 CCR Section 60301 et seq. for the use of recycled water and has developed guidelines for specific uses. Title 22 CCR Section 60304(d)(4) allows the use of undisinfected secondary recycled water for the surface irrigation of fodder and fiber crops and pasture for animals not producing milk for human consumption. BBARWA's Title 22

Engineering Report was initially approved on November 3, 1980, by the California DHS, (now DDW). The Title 22 report was last updated November 4, 1998, to allow for the use of tertiary treated wastewater in the Big Bear Area.

12. The grazing of sheep on the irrigation site has been allowed under certain conditions, as outlined in a letter from Colorado River Basin Water Board staff dated November 15, 1994, and under the conditions shown in Discharge Specification D.22 of this Order.

13. No sewage sludge is discharged at the recycled water reuse site.

14. BBARWA's Self-Monitoring Reports (SMRs) from April 2011 through March 2016 characterize the WWTP effluent as follows:

Constituent	Units	Average	Maximum	Minimum
Flow	MGD	2.01	4.18	1.42
20^{o} C BOD_5[1]	mg/L[2]	6	17	2
TSS[3]	mg/L	13	48	5
pH	s.u.[4]	7.8	8.0	7.4
TDS[5]	mg/L	450	519	354
Nitrate as N	mg/L	3.5	21.6	0.1
Total Nitrogen	mg/L	6.9	28	1.9
Chloride	mg/L	52	61	34
Sulfate	mg/L	40	48	26
Fluoride	mg/L	0.37	0.54	0.24
Boron	mg/L	0.18	0.25	<0.1

Hydrogeologic Conditions at the Lucerne Valley Facility

15. BBARWA installed one groundwater monitoring well in 1979 and three more groundwater monitoring wells in 1991 (MW-1, MW-2 and MW-3). Monitoring well MW-3 replaced the 1979 monitoring well, which was never monitored because the groundwater level is below the bottom of the well. Previous monitoring did not require depth to groundwater monitoring; however, the Discharger's reports indicate that MW-1 is the upgradient well. This Board Order will require depth to groundwater monitoring in order to establish the groundwater gradient.

[1] 5-day biochemical oxygen demand at 20 degrees Celsius.
[2] milligrams per Liter
[3] Total Suspended Solids
[4] Standard pH units
[5] Total Dissolved Solids

16. An irrigation well (14M1) was installed immediately northwest of the overflow ponds in 1986. The distance from well 14M1 to the nearest overflow pond is 180 feet.

17. BBARWA has reported that the depth to groundwater at the Lucerne Valley Facility is a minimum 150 feet below ground surface.

18. Groundwater monitoring data collected from monitoring wells MW-1, MW-2 and MW-3 during the period from 2009 to the present show the following average characteristics:

Constituent	Units	MW-1	MW-2	MW-3
Depth to Groundwater[6]	ft	176	130	141
TDS	mg/L	464	718	619
Total Nitrogen	mg/L	10.6	16.2	17.6
Nitrate as Nitrogen	mg/L	9.4	15.6	17.2
Sulfate	mg/L	63.3	203	173
Chloride	mg/L	106	122	135
Fluoride	mg/L	0.25	0.14	0.25
Boron	mg/L	<0.01	<0.01	<0.01
VOCs – MTBE	ug/L	9.0	ND	ND
VOCs – Methylene Chloride	ug/L	ND	1.4	1.1
VOCs – Bromomethane	ug/L	ND	ND	1.3

19. An analysis of groundwater monitoring data in monitoring wells MW1, MW2 and MW3 from 2000 to the present indicates that concentrations for nitrate, sulfate and chloride are decreasing in the downgradient wells (MW2 and MW3) and increasing in the upgradient well (MW1). This Board Order will require that the Discharger submit a technical report providing an analysis of the water quality impacts by nitrogen and TDS to groundwater resulting from the discharge and to report annual trend monitoring of the data collected in the groundwater monitoring network. The monitoring frequency for total nitrogen and nitrate in the groundwater monitoring wells will be increased from annually to monthly for 12 months and quarterly thereafter to establish groundwater gradient and flow direction. In addition, this Board Order will require annual reporting of nitrogen application of fertilizers and in farming practices and provide a nitrogen and water use balance for the recycled water used on-site.

20. Annual precipitation in the Lucerne Valley region averages about 5.5 inches. Annual evapotranspiration rate is approximately 68 inches.

21. The project lies beyond the toe of a large alluvial fan emanating from the mouth of Cushenbury Canyon in the eastern portion of Lucerne Valley.

[6] Measurement made in 2004.

22. There are several domestic wells in the vicinity of the on-site evaporation/percolation ponds.

23. Water supply to the Big Bear area communities is from numerous groundwater production wells located in Big Bear Valley. TDS in the water supply averages about 280 mg/L based on data reported in the BBARWA's SMRs from 2008 through 2015.

24. Regional groundwater flow in the irrigation and disposal area is generally to the northwest.

25. BBARWA conducted a geotechnical study referenced as *Geotechnical Study, Irrigation Site, Lucerne Valley Area, San Bernardino County, California for Big Bear Area Regional Wastewater Agency, July 29, 1977,* as an initial investigation of the site for use for irrigation. The report shows that the site is underlain by soils consisting of fine to coarse, clean to silty sands containing various amounts of grave from 5 to 24 feet below ground surface. Beneath this, to a depth of 60 to 100 feet below ground surface, the soil consists of fine to medium silty sands containing varying amounts of gravel, and is locally cemented with calcium carbonate accumulated during deposition of the sediments. Bedrock underlies the older alluvium at a depth of 400 to 600 feet.

Basin Plan, Beneficial Uses, and Regulatory Considerations

26. The Water Quality Control Plan for the Colorado River Basin Region of California (Basin Plan), which was adopted on November 17, 1993, and amended on November 13, 2012, designates the beneficial uses of ground and surface waters in this Region, and contains implementation programs and policies to achieve water quality objectives, including narrative objectives for ground water quality, in Chapter 3, section IV, Ground Water Objectives.

27. The discharge is within the Lucerne Hydrologic Unit. The beneficial uses of groundwater in the Lucerne Hydrologic Unit include:

    a. Municipal supply (MUN),

    b. Industrial supply (IND), and

    c. Agricultural supply (AGR).

28. These WDRs implement numeric and narrative water quality objectives for ground and surface waters established by the Basin Plan. The numeric objectives for groundwater designated for municipal and domestic supply are the maximum contaminant levels (MCLs) specified in sections 64431, 64444, and 64678 of Title 22 of the California Code of Regulations (CCR), and the bacteriological limits specified in section 64426.1 of Title 22, CCR.

29. It is the policy of the State of California that every human being has the right to safe, clean, affordable, and accessible water adequate for human consumption, cooking, and sanitary purposes. This order promotes that policy by requiring discharges to meet maximum contaminant levels designed to protect human health and ensure that water is safe for domestic use.

30. Section 13267 of the CWC authorizes the Colorado River Basin Water Board to require technical and monitoring reports. The Monitoring and Reporting Program (MRP) establishes monitoring and reporting requirements to implement federal and state

requirements.

31. This Order establishes WDRs pursuant to Division 7, Chapter 4, Article 4, of the CWC for discharges that are not subject to regulation under Clean Water Act (CWA) section 402 (33 U.S.C. section 1342).

32. Pursuant to CWC section 13263(g), the discharge of waste is a privilege, not a right, and adoption of this Order does not create a vested right to continue the discharge.

33. The discharge authorized by this Board Order, and treatment and storage facilities associated with discharges of treated municipal wastewater, except for discharges of residual sludge and solid waste, are exempt from the requirements of the Consolidated Regulations for Treatment, Storage, Processing, or Disposal of Solid Waste, as set forth in Title 27, CCR, Division 2, Subdivision 1. This exemption is based on section 20090(a) of Title 27, which states in relevant part that discharges of domestic sewage or treated effluent are exempt provided that such discharges are regulated by WDRs, or for which WDRs have been waived, and which are consistent with applicable water quality objectives, and treatment or storage facilities.

Groundwater Degradation

34. State Water Board Resolution 68-16, "Policy with Respect to Maintaining High Quality Waters of the State"(Resolution 68-16) states:

    "Whenever the existing quality of water is better than the quality established in policies as of the date on which such policies become effective, such existing high quality will be maintained until it has been demonstrated to the State that any change will be consistent with maximum benefit to the people of the State, will not unreasonably affect present and anticipated beneficial use of such water and will not result in water quality less than that prescribed in the policies."

    Resolution 68-16 further states:

    "Any activity which produces or may produce a waste or increased volume or concentration of waste and which discharges or proposes to discharge to existing high quality waters will be required to meet waste discharge requirements which will result in the best practicable treatment or control [BPTC] of the discharge necessary to assure that (a) a pollution or nuisance will not occur and (b) the highest water quality consistent with maximum benefit to the people of the State will be maintained."

35. Some degradation of groundwater from the discharge to the evaporation/percolation ponds is consistent with Resolution 68-16, provided that the degradation:

    a. Is confined to a reasonable area;

    b. Is minimized by means of full implementation, regular maintenance, and optimal operation of BPTC measures;

    c. Is limited to waste constituents typically encountered in domestic wastewater; and

    d. Does not result in the loss of any beneficial use as prescribed in the applicable basin plan, or violation of any water quality objective.

36. The discharge of wastewater as permitted by Order R7-2016-0026 and Order R8-2005-

0044 reflects BPTC. The controls assure the discharge does not create a condition of pollution or nuisance, and that water quality will be maintained, which is consistent with the anti-degradation provisions of Resolution No. 68-16. The Discharger incorporates:

a. A WWTP that provides treatment to secondary standards and nitrification/denitrification processes;

b. An operation and maintenance manual;

c. Staffing to assure proper operation and maintenance;

d. A network of groundwater monitoring wells at the recycle site;

e. A requirement for an Irrigation Management Plan; and

f. A standby emergency power generator of sufficient size to operate the treatment plant and ancillary equipment during periods of loss of commercial power.

Accordingly, the discharge as authorized is consistent with the anti-degradation provisions of Resolution 68-16 and the applicable water quality objectives.

Constituents of Concern

37. Constituents in domestic wastewater effluent that present the greatest risk to groundwater quality are nitrogen, coliforms (pathogen-indicator organisms), and TDS. Recycled water used for irrigation at the Lucerne Valley Facility is treated to secondary standards and has undergone substantial removal of soluble organic matter, solids, and nitrogen treatment.

38. Title 22, CCR, section 64431, Maximum Contaminant Level (MCL) for Nitrate plus Nitrite as Nitrogen is 10 mg/L. To account for the fate of transport for the various components of Total Nitrogen, as a conservative value it is assumed that all nitrogen present converts to nitrate/nitrite. BBARWA's SMRs report an average of 6.9 mg/L for Total Nitrogen between April 2011 and March 2015. Prior to the operation of nitrification/denitrification processes at the WWTP, groundwater analyses at the irrigation and disposal site demonstrated degradation by nitrates. This Board Order will require the Discharger to provide a technical report in the form of a study that analyses the impacts to groundwater by the discharge and an evaluation of water quality trends. In addition, this Board Order will implement a monthly average effluent limitation of 10 mg/L for total nitrogen as a means to mitigate groundwater degradation.

39. While secondary treatment reduces fecal coliform densities by 90 to 99%, the remaining organisms in effluent are still 10^5 to 10^6 MPN/100 ml (United States Environmental Protection Agency, Design Manual, Municipal Wastewater Disinfection; October 1986). Given the depth to groundwater, it is not likely that pathogen-indicator bacteria will reach groundwater at densities exceeding those prescribed in Title 22, CCR.

40. The typical incremental addition of dissolved salts from domestic water usage is 150 to 380 mg/L. Domestic water supply to the Big Bear area communities showed an average concentration of about 280 mg/L during the period of 2011 to 2016. From April 2011 to March 2016 treated wastewater discharged had an average TDS concentration of approximately 450 mg/L. Thus, the average TDS increase over the domestic water supply in the discharge during the same time period was about 170 mg/L. Treated wastewater discharged by the WWTP has a TDS limit of a maximum of 400 mg/L above the domestic source water as regulated by Board Order 01-156. This Board Order will

require the Discharger to provide a technical report in the form of a study that analyzes the impacts to groundwater by the discharge and an evaluation of water quality trends. The results of the study will be used to establish an appropriate effluent limitation for TDS.

CEQA and Public Participation

41. In accordance with section 15301, Chapter 3, Title 14, CCR, the issuance of these WDRs, which govern the operation of an existing facility involving negligible or no expansion of use beyond that previously existing, is exempt from the provisions of the California Environmental Quality Act (CEQA, Pub. Resources Code, section 21000 et seq.).

42. The Colorado River Basin Water Board has notified the Discharger and all known interested agencies and persons of its intent to draft WDRs for this discharge, and has provided them with an opportunity for a public meeting and an opportunity to submit comments.

43. The Colorado River Basin Water Board, in a public meeting, heard and considered all comments pertaining to this discharge.

IT IS HEREBY ORDERED, that Board Order 01-156 is rescinded upon the effective date of this Order, except for enforcement purposes, and, in order to meet the provisions contained in Division 7 of the California Water Code, and regulations adopted thereunder, the Discharger shall comply with the following:

A. Effluent Limitations

1. Effluent discharged into the overflow evaporation/percolation ponds for disposal shall not exceed the following effluent limits:

Constituent	Units	30-Day Arithmetic Mean	7-Day Arithmetic Mean	Daily Maximum
20^{o} C BOD_5	mg/L	30	45	-----
Total Suspended Solids	mg/L	30	45	-----
Chloride	mg/L	60	-----	80
Sulfate	mg/L	60	-----	80
Boron	mg/L	-----	-----	0.75
Total Nitrogen	mg/L	10	-----	-----

2. The 30-day average daily dry weather discharge for irrigation shall not exceed 4.8 MGD.

3. Effluent discharge for irrigation shall not have a pH below 6.0 or above 9.0.

B. Groundwater Limitations

1. Discharge at the Lucerne Valley Facility shall not cause groundwater to:

   a. Contain constituents in excess of California MCLs, as set forth in the California Code

of Regulations, Title 22, section 64426.1 for bacteriological constituents; section 64431 for inorganic chemicals; section 64444 for organic chemicals; and section 64678 for determination of exceedances of lead and copper action levels.

b. Contain taste or odor-producing substances in concentrations that adversely affect beneficial uses as a result of human activity.

C. Discharge Prohibitions

1. Discharge of waste classified as "hazardous", as defined in Title 23, CCR, section 2521(a), or "designated", as defined in California Water Code section 13173, is prohibited.

2. Discharge of treated wastewater at a location other than the designated disposal areas or as recycled water used for irrigation at approved use areas, is prohibited.

3. The discharge of recycled water to any drainage courses or surface waters is prohibited.

4. Discharge of waste to land not owned or authorized for such use by the Discharger is prohibited.

5. Surfacing or ponding of wastewater outside of the designated disposal locations is prohibited.

6. Bypass, overflow, discharge, or spill of untreated or partially treated waste is prohibited.

7. Application recycled water and fertilizers containing nitrogen at a rate greater than the agronomic uptake rate of the crops grown is prohibited.

D. Discharge Specifications

1. The discharge shall not cause pollution or nuisance as defined in sections 13050(l) and 13050(m) of Division 7 of the California Water Code, respectively.

2. A minimum depth of freeboard of two (2) feet shall be maintained at all times in the overflow earthen basins and concrete-lined reservoir.

3. The overflow ponds shall be managed to prevent breeding of mosquitoes. In particular:
    a. An erosion control program should assure that small coves and irregularities are not created around the perimeter of the water surface.
    b. Weeds shall be minimized through control of water depth, harvesting, or herbicides.
    c. Dead algae, vegetation, and debris shall not accumulate on the water

4. All storage and disposal areas shall be designed, constructed, operated, and maintained to prevent inundation or washout due to floods with a 100-year return frequency.

5. The overflow ponds shall have sufficient capacity to accommodate allowable wastewater flow, design seasonal precipitation, ancillary inflow, and infiltration during the non-irrigation season. Design seasonal precipitation shall be based on total

annual precipitation using a return period of 100 years, distributed monthly in accordance with historical rainfall patterns.

6. Public contact with non-disinfected wastewater shall be precluded through such means as fences, signs, and other acceptable alternatives. The non-disinfected wastewater is not approved for off-site distribution. Conspicuous signs shall be posted in a prominent location in each area where non-disinfected wastewater is stored on-site. Each sign or label with "Non-disinfected wastewater - No body contact or drinking" wording shall be displayed as well as the international warning symbol.

7. Objectionable odors originating at the Lucerne Valley Facility shall not be perceivable beyond the limits of the wastewater treatment and disposal area.

8. The overflow ponds and concrete-lined reservoir shall be maintained so they will be kept in aerobic conditions.

9. The dissolved oxygen content in the upper zone (one foot) of the concrete reservoir and overflow ponds shall not be less than 1.0 mg/L.

10. There shall be no surface flow of wastewater away from the designated disposal areas.

11. On-site wastes, including windblown spray from recycled water application, shall be strictly confined to the lands specifically designated for the disposal operation, and on-site irrigation practices shall be managed so there is no runoff of effluent from irrigated areas.

12. No irrigation with, or impoundment of, undisinfected secondary recycled water shall take place within 150 feet of any domestic water supply well.

13. No spray irrigation of any recycled water shall take place within 100 feet of a residence or a place where public exposure could be similar to that of a park, playground or schoolyard.

14. Except as allowed under Section 7604 of Title 17, California Code of Regulations, no physical connection shall be made or allowed to exist between any recycled water system and any separate system conveying potable water.

15. Undisinfected secondary recycled water, as defined in Title 22, Section 60301.900 is limited only for irrigation in the following applications:

    a. Orchards where the recycled water does not come into contact with the edible portion of the crop,

    b. Vineyards where the recycled water does not come into contact with the edible portion of the crop,

    c. Non-food bearing trees (Christmas tree farms are included in this category provided no irrigation with recycled water occurs for a period of 14 days prior to harvesting or allowing access by the general public),

    d. Fodder and fiber crops and pasture for animal not producing milk for human consumption,

e. Seed crops not eaten by humans,

f. Food crops that must undergo commercial pathogen-destroying processing before being consumed by humans, and

g. Ornamental nursery stock and sod farms provided no irrigation with recycled water occurs for a period of 14 days prior to harvesting, retail sale, or allowing access by the general public.

16. No recycled water used for irrigation, or soil that has been irrigated with recycled water, shall come into contact with edible portions of food crops eaten raw by humans.

17. The storage, delivery, or use of recycled water shall not individually or collectively, directly or indirectly, result in pollution, or adversely affect water quality, as defined in the CWC.

18. The delivery or use of recycled water shall be in conformance with the reclamation criteria contained in Title 22, or amendments thereto, for the irrigation of food crops, irrigation of fodder, fiber, and seed crops, landscape irrigation, supply of recreational impoundments and ground water recharge.

19. Prior to delivering recycled water to any new user, BBARWA shall submit to the Colorado River Basin Water Board a report discussing any new distribution system being constructed by the Discharger to provide service to the new user.

20. Recycled water shall not be delivered to any new user who has not first received a discharge permit from the Colorado River Basin Water Board and approval from the SWRCB's Division of Drinking Water.

21. Treated or untreated sludge or similar solid waste materials shall be disposed at locations approved by the Colorado River Basin Water Board's Executive Officer.

22. Grazing of sheep on the irrigation site is allowed only under the following conditions, unless otherwise approved by the Colorado River Basin Water Board 's Executive Officer:

    a. Grazing will only be conducted in October or November after the last cutting of hay has been baled;

    b. Grazing animals will not be allowed into a portion of the site until 10 days after it was last irrigated;

    c. Temporary fences will be erected to contain the grazing animals in an area of 40 acres or less;

    d. Only ewes that are about to lamb or ewes with newly born will be grazed;

    e. No animals will be sold for slaughter within 90 days after grazing.

    f. No milk produced by sheep that have grazed at the irrigation site shall be used for human consumption.

E. Special Provisions

1. Within **three months** of the adoption of this Board Order, the Discharger shall submit a technical report that is a work plan, for approval by the Colorado River Basin Water

Board's Executive Officer, to conduct a study of the groundwater in the vicinity of the recycled water irrigation use site. The objective of the study shall be to address the impacts that the discharges to unlined ponds and the irrigation area have on areal groundwater quality. The Discharger shall submit the final technical report containing the results of the study within **18 months** of the adoption of this Board Order and shall propose recommendations to mitigate the effects of nitrogen loading to groundwater and propose an appropriate effluent limit for TDS.

2. Within six months of the adoption of this Board Order, the Discharger shall prepare and submit an Irrigation Management Plan that includes a water balance and nutrient balance to assure that recycled water is applied at appropriate rates. The Irrigation Management Plan shall be submitted for approval by the Colorado River Basin Water Board's Executive Officer.

3. Within **nine months** of the adoption of this Order, the Discharger shall submit to the Colorado River Basin Water Board office a technical report that includes a copy of the Maintenance and Operations Manual for the Lucerne Valley Facility.

F. Standard Provisions

1. The Discharger shall comply with all of the conditions of this Board Order. Noncompliance is a violation of the Porter-Cologne Water Quality Control Act (CWC, section 13000 et seq.), and is grounds for enforcement action.

2. The Discharger shall comply with Monitoring and Reporting Program R7-2016-0026 and future revisions thereto as specified by the Colorado River Basin Water Board's Executive Officer.

3. The Discharger shall comply with the Electronic Submittal of Information (ESI) requirements by submitting all correspondence and reports required under Monitoring and Reporting Program (MRP) R7-2016-0026, and future revisions thereto, including groundwater monitoring data and discharge location data (latitude and longitude), correspondence, and pdf monitoring reports to the State Water Resources Control Board GeoTracker https://geotracker.waterboards.ca.gov/ database. Documents that are normally mailed by the Discharger, such as regulatory documents, narrative technical monitoring program reports, and such reports submissions, materials, data, and correspondence, to the Colorado River Basin Water Board shall also be uploaded into GeoTracker in the appropriate Microsoft software application, such as word, excel, or an Adobe Portable Document Format (PDF) file. Large documents are to be split into manageable file sizes appropriately labelled and uploaded into GeoTracker.

4. All technical reports required in conjunction with this Order are required pursuant to Section 13267 of the CWC, and shall include a statement by the Discharger, or an authorized representative of the Discharger, certifying under penalty of perjury under the laws of the State of California, that the report is true, complete, and accurate.

5. In accordance with California Business and Professions Code Sections 6735, 7835, and 7835.1, engineering and geologic evaluations and judgments shall be performed by or under the direction of California registered professionals (i.e., civil engineer, engineering geologist, geologist, etc.) competent and proficient in the fields pertinent to the required activities. All technical reports specified herein that contain work plans, that describe the conduct of investigations and studies, or that contain technical conclusions and

recommendations concerning engineering and geology shall be prepared by or under the direction of appropriately qualified professionals, even if not explicitly stated. Each technical report submitted by the Discharger shall contain a statement of qualifications of the responsible licensed professionals as well as the professional's signature and/or stamp of the seal. Additionally, to the extent that preparation of a required technical report involves field activities, field activities shall be conducted under the direct supervision of one or more of these professionals.

6. The Discharger shall not cause degradation of any water supply in accordance with State Water Board Resolution 68-16.

7. Standby power generating facilities shall be available to operate the plant during a commercial power failure.

8. Adequate measures shall be taken to assure that flood or surface drainage waters do not erode or otherwise render portions of the discharge facilities inoperable.

9. The use of recycled water at the Lucerne Valley Facility shall be supervised by persons possessing certification of appropriate grade pursuant to section 3680, Chapter 26, Division 3, Title 23 of the California Code of Regulations.

10. The Discharger shall at all times properly operate and maintain all systems and components of collection, treatment and control, installed or used by the Discharger to achieve compliance with this Board Order. Proper operation and maintenance includes effective performance, adequate process controls, and appropriate quality assurance procedures. This provision requires the operation of backup or auxiliary facilities/systems when necessary to achieve compliance with this Board Order. All systems in service or reserved shall be inspected and maintained on a regular basis. Records of inspections and maintenance shall be retained, and made available to the Colorado River Basin Water Board's Executive Officer on request.

11. The Discharger shall ensure that all site-operating personnel are familiar with the content of this Board Order, and shall maintain a copy of this Board Order at the site.

12. The Discharger shall allow the Colorado River Basin Water Board, or an authorized representative, upon presentation of credentials and other documents as may be required by law, to:

    a. Enter the premises regulated by this Board Order, or the place where records are kept under the conditions of this Board Order;

    b. Have access to and copy, at reasonable times, records kept under the conditions of this Board Order;

    c. Inspect at reasonable times any facilities, equipment (including monitoring and control equipment), practices, or operations regulated or required under this Board Order; and

    d. Sample or monitor at reasonable times, for the purpose of assuring compliance with this Board Order or as otherwise authorized by the California Water Code, any substances or parameters at this location.

13. Ponds shall be managed to prevent breeding of mosquitoes. In particular,

    a. An erosion control program should assure that small coves and irregularities are not

created around the perimeter of the water surface.

b. Weeds shall be minimized through control of water depth, harvesting, or herbicides.

c. Dead algae, vegetation, and debris shall not accumulate on the water surface.

14. Disposal of oil and grease, biosolids, screenings, and other solids collected from liquid wastes shall be pursuant to Title 27, and the review and approval of the Colorado River Basin Water Board Executive Officer.

15. Any proposed change in use or disposal of biosolids requires the approval of the Colorado River Basin Water Board Executive Officer, and U.S. Environmental Protection Agency Regional Administrator, who must be notified at least 90 days in advance of the change.

16. Sludge use and disposal shall comply with Federal and State laws and regulations, including permitting requirements, and technical standards in 40 CFR Part 503. If the State and Colorado River Basin Water Boards are delegated the authority to implement 40 CFR Part 503 regulations, this Order may be revised to incorporate appropriate time schedules and technical standards. The Discharger shall comply with the standards and time schedules in 40 CFR part 503, whether or not part of this Order.

17. The Discharger shall provide a plan as to the method, treatment, handling and disposal of sludge that is consistent with all State and Federal laws and regulations and obtain prior written approval from the Colorado River Basin Water Board specifying location and method of disposal, before disposing of treated or untreated sludge, or similar solid waste.

18. The Discharger shall maintain a permanent log of all solids hauled away from the treatment facility for use/disposal elsewhere and shall provide a summary of the volume, type (screenings, grit, raw sludge, digested sludge), use (agricultural, composting, etc.), and the destination in accordance with the MRP of this Board Order. Sludge that is stockpiled at the treatment facility shall be sampled and analyzed for those constituents listed in the sludge monitoring section of the MRP of this Board Order and as required by Title 40, Code of Federal Regulations, Part 503. The results of the analyses shall be submitted to the Colorado River Basin Water Board as part of the MRP.

19. The Discharger shall provide a report to the Colorado River Basin Water Board when it determines that the plant's average dry-weather flow rate for any month exceeds 80 percent of the design capacity. The report should indicate what steps, if any, the Discharger intends to take to provide for the expected wastewater treatment capacity necessary when the plant reaches design capacity.

20. Prior to implementing a modification that results in a material change in the quality or quantity of wastewater treated or discharged, or a material change in the location of discharge, the Discharger shall report all pertinent information in writing to the Colorado River Basin Water Board, and obtain revised requirements.

21. Prior to a change in ownership or management of the Lucerne Valley Facility, the Discharger shall transmit a copy of this Board Order to the succeeding owner/operator, and forward a copy of the transmittal letter to the Colorado River Basin Water Board.

22. The Discharger shall provide adequate notice to the Colorado River Basin Water Board

Executive Officer of the following:

a. Any substantial change in the volume or character of pollutants introduced into any treatment facility described in the Findings of this Board Order, by an existing or new source; and

b. Any planned physical alteration or addition to the facilities described in this Board Order, or change planned in the Discharger's sludge use or disposal practice, where such alterations, additions, or changes may justify the application of Board Order conditions that are different from or absent in the existing Board Order, including notification of additional disposal sites not reported during the Board Order application process, or not reported pursuant to an approved land application plan.

23. The Discharger shall report orally, any noncompliance that may endanger human health or the environment. The noncompliance shall be reported immediately to the Colorado River Basin Water Board's Executive Officer at (760) 346-7491, and the California Office of Emergency Services at (800) 852-7550 as soon as:

    a. The Discharger has knowledge of the discharge,

    b. Notification is possible, and

    c. Notification will not substantially impede cleanup or other emergency measures.

    During non-business hours, the Discharger shall leave a message on the Colorado River Basin Water Board's office voice recorder at the above listed number. Incident information shall be provided orally as soon as possible and within 24 hours from the time the Discharger becomes aware of the incident. A written report shall also be provided within five (5) business days of the time the Discharger becomes aware of the incident. The written report shall contain a description of the noncompliance and its cause, the period of noncompliance, the anticipated time to achieve full compliance, and the steps taken or planned, to reduce, eliminate, and prevent recurrence of the noncompliance. The Discharger shall report all intentional or unintentional spills in excess of one thousand (1,000) gallons occurring within the Colorado River Basin Water Board's jurisdiction, including the Lucerne Valley Facility or disposal line, in accordance with the above time limits.

24. The Discharger shall report all instances of noncompliance. Reports of noncompliance shall be submitted with the Discharger's next scheduled SMRs or earlier if requested by the Colorado River Basin Water Board's Executive Officer, or if required by an applicable standard for sludge use and disposal.

25. By-pass (i.e., the intentional diversion of waste streams from any portion of the treatment facilities, except diversions designed to meet variable effluent limits) is prohibited. The Colorado River Basin Water Board may take enforcement action against the Discharger for by-pass unless:

    a. By-pass was unavoidable to prevent loss of life, personal injury, or severe property damage. Severe property damage means substantial physical damage to property, damage to the treatment facilities that causes them to be inoperable, or substantial and permanent loss of natural resources reasonably expected to occur in the absence of a by-pass. Severe property damage does not mean economic loss caused by delays in production; and

    There were no feasible alternatives to by-pass, such as the use of auxiliary treatment

facilities or retention of untreated waste. This condition is not satisfied if adequate back-up equipment was not installed to prevent by-pass occurring during equipment downtime, or preventive maintenance.

b. By-pass is:

   i. Required for essential maintenance to assure efficient operation; and

   ii. Neither effluent nor receiving water limitations are exceeded; and

   iii. The Discharger notifies the Colorado River Basin Water Board ten (10) days in advance.

26. In the event of an unanticipated by-pass, the Discharger shall immediately report the incident to the Colorado River Basin Water Board. During non-business hours, the Discharger shall leave a message on the Colorado River Basin Water Board office voice recorder. A written report shall be provided within five business days the Discharger is aware of the incident. The written report shall include a description of the by-pass, any noncompliance, the cause, period of noncompliance, anticipated time to achieve full compliance, and steps taken or planned, to reduce, eliminate, and prevent recurrence of the noncompliance.

27. Federal regulations for storm water discharges require specific categories of facilities which discharge storm water associated with industrial activity (storm water) to obtain National Pollutant Discharge Elimination System (NPDES) permits and to implement Best Conventional Pollutant Technology (BCT) and Best Available Technology Economically Achievable (BAT) to reduce or eliminate industrial storm water pollution.

28. All storm water discharges from this facility must comply with the lawful requirements of municipalities, counties, drainage districts, and other local agencies, regarding discharges of storm water to storm water drain systems or other courses under their jurisdiction.

29. Storm water discharges from the facility shall not cause or threaten to cause pollution or contamination.

30. Storm water discharges from the facility shall not contain hazardous substances equal to or in excess of a reportable quantity listed in 40 CFR Part 117 and/or 40 CFR Part 302.

31. The Discharger is the responsible party for the waste discharge requirements and the monitoring and reporting program for the facility. The Discharger shall comply with all conditions of these waste discharge requirements. Violations may result in enforcement actions, including Colorado River Basin Water Board Orders or court orders, requiring corrective action or imposing civil monetary liability, or in modification or revocation of these waste discharge requirements by the Colorado River Basin Water Board.

32. This Board Order does not authorize violation of any federal, state, or local laws or regulations.

33. This Board Order does not convey property rights of any sort, or exclusive privileges, nor does it authorize injury to private property or invasion of personal rights, or infringement of federal, state, or local laws or regulations.

34. This Board Order may be modified, rescinded, or reissued, for cause. The filing of a

request by the Discharger for a Board Order modification, rescission or reissuance, or notification of planned changes or anticipated noncompliance, does not stay any Board Order condition. Causes for modification include a change in land application plans, or sludge use or disposal practices, and adoption of new regulations by the State or Colorado River Basin Water Board (including revisions to the Basin Plan), or Federal government.

I, Jose L. Angel, Executive Officer, do hereby certify the foregoing is a full, true and correct copy of an Order adopted by the California Regional Water Quality Control Board, Colorado River Basin Region, on June 30, 2016.

Jose L. Angel

JOSE L. ANGEL P.E.
Executive Officer

CALIFORNIA REGIONAL WATER QUALITY CONTROL BOARD
COLORADO RIVER BASIN REGION

MONITORING AND REPORTING PROGRAM R7-2016-0026
FOR
BIG BEAR AREA REGIONAL WASTEWATER AGENCY, OWNER/OPERATOR
EXPORT OF RECYCLED WATER TO LUCERNE VALLEY
Lucerne Valley – San Bernardino County

Location of Discharge:
Section 14, T4N, R1E, SBB&M

A. Monitoring

1. This Monitoring and Reporting Program (MRP) describes requirements for monitoring a wastewater system and groundwater quality (when needed). This MRP is issued pursuant to California Water Code (CWC) section 13267. The Discharger shall not implement any changes to this MRP unless and until a revised MRP is issued by the Executive Officer.

2. Water Code section 13267 states, in part:

   "In conducting an investigation specified in subdivision (a), the Colorado River Basin Water Board may require that any person who has discharged, discharges, or is suspected of having discharged or discharging, or who proposes to discharge waste within its region, or any citizen or domiciliary, or political agency or entity of this state who has discharged, discharges, or is suspected of having discharged or discharging, or who proposes to discharge, waste outside of its region that could affect the quality of waters within its region shall furnish, under penalty of perjury, technical or monitoring program reports which the Colorado River Basin Water Board requires. The burden, including costs, of these reports shall bear a reasonable relationship to the need for the report and the benefits to be obtained from the reports. In requiring those reports, the Colorado River Basin Water Board shall provide the person with a written explanation with regard to the need for the reports, and shall identify the evidence that supports requiring that person to provide the reports."

3. Water Code section 13268 states, in part:

   "(a) (1) Any person failing or refusing to furnish technical or monitoring program reports as required by subdivision (b) of section 13267, or failing or refusing to furnish a statement of compliance as required by subdivision (b) of section 13399.2, or falsifying any information provided therein, is guilty of a misdemeanor, and may be liable civilly in accordance with subdivision (b). (b) (1) Civil liability may be administratively imposed by a Colorado River Basin Water Board in accordance with Article 2.5 (commencing with section 13323) of Chapter 5 for a violation of subdivision (a) in an amount which shall not exceed one thousand dollars ($1,000) for each day in which the violation occurs."

4. BBARWA owns and operates the wastewater system that is subject to Board Order R7-2016-0026. The reports are necessary to ensure that the Discharger complies with the Order. Pursuant to Water Code section 13267, the Discharger shall implement the MRP and shall submit the monitoring reports described herein.

5. All samples shall be representative of the volume and nature of the discharge or matrix of material sampled. The time, date, and location of each grab sample shall be recorded

on the sample chain of custody form. If composite samples are collected, the basis for sampling (time or flow weighted) shall be approved by Colorado River Basin Water Board staff.

6. Field test instruments (such as those used to test pH, dissolved oxygen, and electrical conductivity) may be used provided that:
   a. The user is trained in proper use and maintenance of the instruments;
   b. The instruments are field calibrated prior to monitoring events at the frequency recommended by the manufacturer;
   c. Instruments are serviced and/or calibrated by the manufacturer at the recommended frequency; and
   d. Field calibration reports are submitted as described in the "Reporting" section of this MRP.

7. The collection, preservation and holding times of all samples shall be in accordance with U. S. Environmental Protection Agency (USEPA) approved procedures. Unless otherwise approved by the Colorado River Basin Water Board's Executive Officer, all analyses shall be conducted by a laboratory certified by the State Water Resources Control Board, Division of Drinking Water. All analyses shall be conducted in accordance with the latest edition of the "Guidelines Establishing Test Procedures for Analysis of Pollutants" (40 CFR Part 136), promulgated by the USEPA.

8. All monitoring instruments and devices used by the Discharger to fulfill the prescribed monitoring program shall be properly maintained and calibrated as necessary to ensure their continued accuracy. In the event that continuous monitoring equipment is out of service for period greater than 24-hours, the Discharger shall obtain representative grab samples each day the equipment is out of service. The Discharger shall correct the cause(s) of failure of the continuous monitoring equipment as soon as practicable. The Discharger shall report the period(s) during which the equipment was out of service and if the problem has not been corrected, shall identify the steps which the Discharger is taking or proposes to take to bring the equipment back into service and the schedule for these actions.

9. The Discharger shall retain records of all monitoring information, including all calibration and maintenance records and all original strip chart recordings for continuous monitoring instrumentation, copies of all reports required by this Board Order, and records of all data used to complete the application for this Board Order, for a period of at least five (5) years from the date of the sample, measurement, report or application. This period may be extended by request of the Colorado River Basin Water Board's Executive Officer at any time. Records of monitoring information shall include:
   a. The date, exact place, and time of sampling or measurement(s);
   b. The individual(s) who performed the sampling or measurement(s);
   c. The date(s) analyses were performed;
   d. The individual(s) who performed the analyses;
   e. The analytical techniques or method used; and
   f. The results of such analyses.

10. Samples shall be collected at the location specified in the WDRs. If no location is

specified, sampling shall be conducted at the most representative sampling point available.

11. Given the monitoring frequency prescribed by MRP R7-2016-0026, if only one sample is available for a given reporting period, compliance with monthly average, or weekly average Discharge Specifications, will be determined from that sample.

12. If the facility is not in operation, or there is no discharge during a required reporting period, the Discharger shall forward a letter to the Colorado River Basin Water Board indicating that there has been no activity during the required reporting period.

Effluent Monitoring

13. Representative samples of the undisinfected secondary recycled water shall be taken at the WWTP. The samples shall be analyzed for the following constituents:

Constituent	Units	Type of Sample	Monitoring Frequency	Reporting Frequency
Irrigation Flow	MGD	Flow Meter Reading	Daily	Monthly
20°C BOD_5	mg/L	24 Hr. Composite	2x/Month	Monthly
Total Suspended Solids	mg/L	24 Hr. Composite	2x/Month	Monthly
pH	s.u. [1]	Grab	Daily	Monthly
Dissolved Oxygen[2]	mg/L	Grab	Monthly	Monthly
Total Dissolved Solids	mg/L	24 Hr. Composite	Monthly	Monthly
Sulfate (SO_4)	mg/L	24 Hr. Composite	Monthly	Monthly
Chloride	mg/L	24 Hr. Composite	2x/Month	Monthly
Fluoride (F)	mg/L	24 Hr. Composite	Monthly	Monthly
Nitrate (NO_3-N) as N	mg/L	24 Hr. Composite	Monthly	Monthly
Total Nitrogen	mg/L	24 Hr. Composite	Monthly	Monthly
VOCs[3]	µg/L[4]	24 Hr. Composite	Annually	Annually

Overflow Pond Monitoring

14. During months when the overflow evaporation/percolation ponds are not used, the Discharger shall report that there has been no activity. During months when the overflow evaporation percolation ponds are in use, the ponds shall be monitored according to the following schedule:

[1] standard pH units
[2] Dissolved Oxygen shall be monitored at the upper one foot layer of the storage or percolation ponds.
[3] Analysis of Volatile Organic Compounds is to be accomplished using the USEPA test methods 601, 602 or 624
[4] micrograms per liter

Constituent	Units	Type of Sample	Monitoring Frequency	Reporting Frequency
Flow Quantity	MGD	Flow Measurement	Daily	Monthly
Dissolved Oxygen	mg/L	Grab	Twice Monthly	Monthly
pH	s.u.	Grab	Twice Monthly	Monthly
Total Dissolved Solids	mg/L	Grab	Twice Monthly	Monthly
Freeboard	ft	Measurement	Twice Monthly	Monthly

Groundwater Monitoring

15. The groundwater monitoring wells shall be monitored according to the following schedule:

Constituent	Units	Type of Sample	Monitoring[5] Frequency	Reporting Frequency
Depth to Groundwater	ft (msl)[6]	Measurement	Monthly	Monthly
Groundwater Gradient[7]	NA	Direction	Monthly	Monthly
Total Nitrogen	mg/L	Grab	Monthly	Monthly
Nitrate as N	mg/L	Grab	Monthly	Monthly
Chloride	mg/L	Grab	Monthly	Monthly
Fluoride	mg/L	Grab	Monthly	Monthly
Sulfate	mg/L	Grab	Monthly	Monthly
Total Dissolved Solids	mg/L	Grab	Monthly	Monthly
Boron	mg/L	Grab	Monthly	Monthly
VOCs	μg/L	Grab	Annually	Annually

Domestic Water Supply Monitoring

16. The domestic water supply shall be a flow weighted composite sample monitored at the water supply production wells in Big Bear Valley and include notations of which wells are non-operating for a reporting period and in accordance to the following schedule:

Constituent	Units	Type of Sample	Monitoring Frequency	Reporting Frequency
Total Dissolved Solids	mg/L	Grab	Annually	Annually

[5] Groundwater monitoring shall be performed monthly for the first 12 months and quarterly thereafter.
[6] Above mean sea level.
[7] Groundwater flow direction.

B. Reporting

1. The Discharger shall inspect and document any operation/maintenance problems by inspecting each unit process. Operation and Maintenance reports shall be submitted to the Colorado River Basin Water Board Office annually, containing documentation showing the calibration of flow meters and equipment as performed in a timely manner, modifications and updates to the Operation and Maintenance Manual, and modifications and updates to the Agency's waste water ordinance or rules and regulations.

2. The Discharger shall annually report a trend monitoring analysis for total nitrogen and nitrates in the groundwater in the vicinity of the recycled water use site. The analysis shall be reported with the Discharger's annual Self-Monitoring Report (SMR).

3. The Discharger shall provide an annual nitrogen balance for the recycled water use site which includes nitrogen loading by application of recycled water and the use of fertilizers for farming. Nitrogen balance shall consider nitrogen uptake by crops grown and provide documentation of crop-specific nitrogen uptake rates. The analysis shall be reported with the Discharger's annual SMR.

4. The Discharger shall provide an operator certification status update including number of staff and grade certification annually.

5. SMRs shall be certified under penalty of perjury to be true and correct, and shall contain the required information at the frequency designated in this MRP.

6. Each Report must contain an affirmation in writing that:

   "All analyses were conducted at a laboratory certified for such analyses by and in accordance with current USEPA procedures or as specified in this Monitoring and Reporting Program."

7. Each Report shall contain the following completed declaration:

   "I certify under the penalty of law that this document, including all attachments and supplemental information, was prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gathered and evaluated the information submitted. I have personally examined and am familiar with the information submitted in this document, and that based on my inquiry of those individuals immediately responsible for obtaining the information, I believe that the information is true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of a fine and imprisonment.

   Executed on the _____day of _____ at _____

   _____(Signature)

   _____(Title)"

8. The SMRs, and other information requested by the Colorado River Basin Water Board, shall be signed by a principal executive officer or ranking elected official.

9. A duly authorized representative of the Discharger may sign the documents if:

   a. The authorization is made in writing by the person described above;

b. The authorization specified an individual or person having responsibility for the overall operation of the regulated disposal system; and

c. The written authorization is submitted to the Colorado River Basin Water Board's Executive Officer.

10. The Discharger shall attach a cover letter to the SMRs. The information contained in the cover letter shall clearly identify violations of the WDRs; discuss corrective actions taken or planned and the proposed time schedule of corrective actions. Identified violations should include a description of the requirement that was violated and a description of the violation.

11. Daily, weekly, and monthly monitoring shall be included in the monthly monitoring report. Monthly monitoring reports shall be submitted to the Colorado River Basin Water Board by the 15th day of the following month. Quarterly monitoring reports shall be submitted by January 15th, April 15th, July 15th and October 15th. Annual monitoring reports shall be submitted by January 31st of the following year.

12. The Discharger shall comply with the Electronic Submittal of Information (ESI) requirements by submitting all correspondence and reports required under Monitoring and Reporting Program (MRP) R7-2016-0026, and future revisions thereto, including groundwater monitoring data and discharge location data (latitude and longitude), correspondence, and pdf monitoring reports to the State Water Resources Control Board GeoTracker database. Documents that are 2.0 MB or larger should be broken down into smaller electronic files, labelled properly and uploaded into GeoTracker.

1 INTRODUCTION AND PURPOSE

Big Bear Area Regional Wastewater Agency (BBARWA) collects and treats the wastewater for its Member Agencies (the City of Big Bear Lake, Big Bear City Community Services District, and San Bernardino County on behalf of Service Area 53B) in the Big Bear Valley in the San Bernardino Mountains of California. BBARWA owns and operates a 4.9 million gallon per day (MGD) capacity wastewater treatment plant (WWTP) located just south of Baldwin Lake on the east side of the Valley. The WWTP currently treats approximately 2.2 MGD of municipal wastewater.

The WWTP discharge is currently regulated by two regulatory boards and discharge permits:

- Santa Ana Region of the California Regional Water Quality Control Board (RWQCB) under Waste Discharge and Producer/User Water Recycling Requirement (WDR) Order No. R8-2005-0044 (Santa Ana WDR), issued on June 24, 2005. The Santa Ana WDR regulates two discharge points in the Big Bear Valley.
- Colorado River Basin RWQCB under WDR Order No. R7-2016-0026 (Colorado River Basin WDR), issued on June 30, 2016. The Colorado River Basin WDR regulates one discharge point in the Lucerne Valley.

The Colorado River Basin WDR and the Lucerne Valley discharge point are the subject of this report.

BBARWA's treated undisinfected secondary effluent is discharged to a 480-acre site in Lucerne Valley (Lucerne Valley Facility) for crop irrigation. Use of treated effluent for crop irrigation at the Lucerne Valley Facility began in 1980 and 100% of the WWTP effluent is currently discharged to this location. The Lucerne Valley Facility also includes two overflow ponds that are used to dispose of excess treated effluent by percolation and evaporation.

As required by Special Provision No. 2 of the recently adopted Colorado River Basin WDR, BBARWA must prepare and submit an Irrigation Management Plan for the Lucerne Valley Facility that includes a water balance and nutrient balance to assure that recycled water is applied at appropriate rates.

This Irrigation Management Plan (Plan) provides background information on the Lucerne Valley Facility, BBARWA's wastewater effluent characteristics, and historic water and nutrient balances. For the purposes of this Plan, the nutrient balance is limited to nitrogen. This plan was originally prepared in 2016 and was updated in 2021 to cover the period from January 2005 to December 2020.

2 LUCERNE VALLEY FACILITY CHARACTERISTICS

2.1 SITE OVERVIEW

The Lucerne Valley Facility is a 480-acre site owned by BBARWA and located near the intersection of Camp Rock Road and Highway 247 (Old Woman Springs Road) in Lucerne Valley, CA, as shown in Figure 1. This site is located approximately 17 miles north of BBARWA's WWTP.

The Lucerne Valley Facility is surrounded by a barbed wire fence to restrict public access to the farm. Warning signs are clearly posted to inform the public that non-disinfected recycled water is used at this site, as shown in Figure 2.

2.1.1 Onsite Wells

There are three monitoring wells located onsite. Monitoring Well 1 is located along the south eastern side of the farm and Monitoring Wells 2 and 3 are located along the north western side of the farm, as shown in Figure 3.

Well 14, shown in Figure 3, is used onsite exclusively for non-potable uses. Bottled water serves as the exclusive potable water source onsite, so there is no potential for cross connection of the recycled water system with a potable water piping system.

All wastewater generated onsite is disposed of using a septic system.

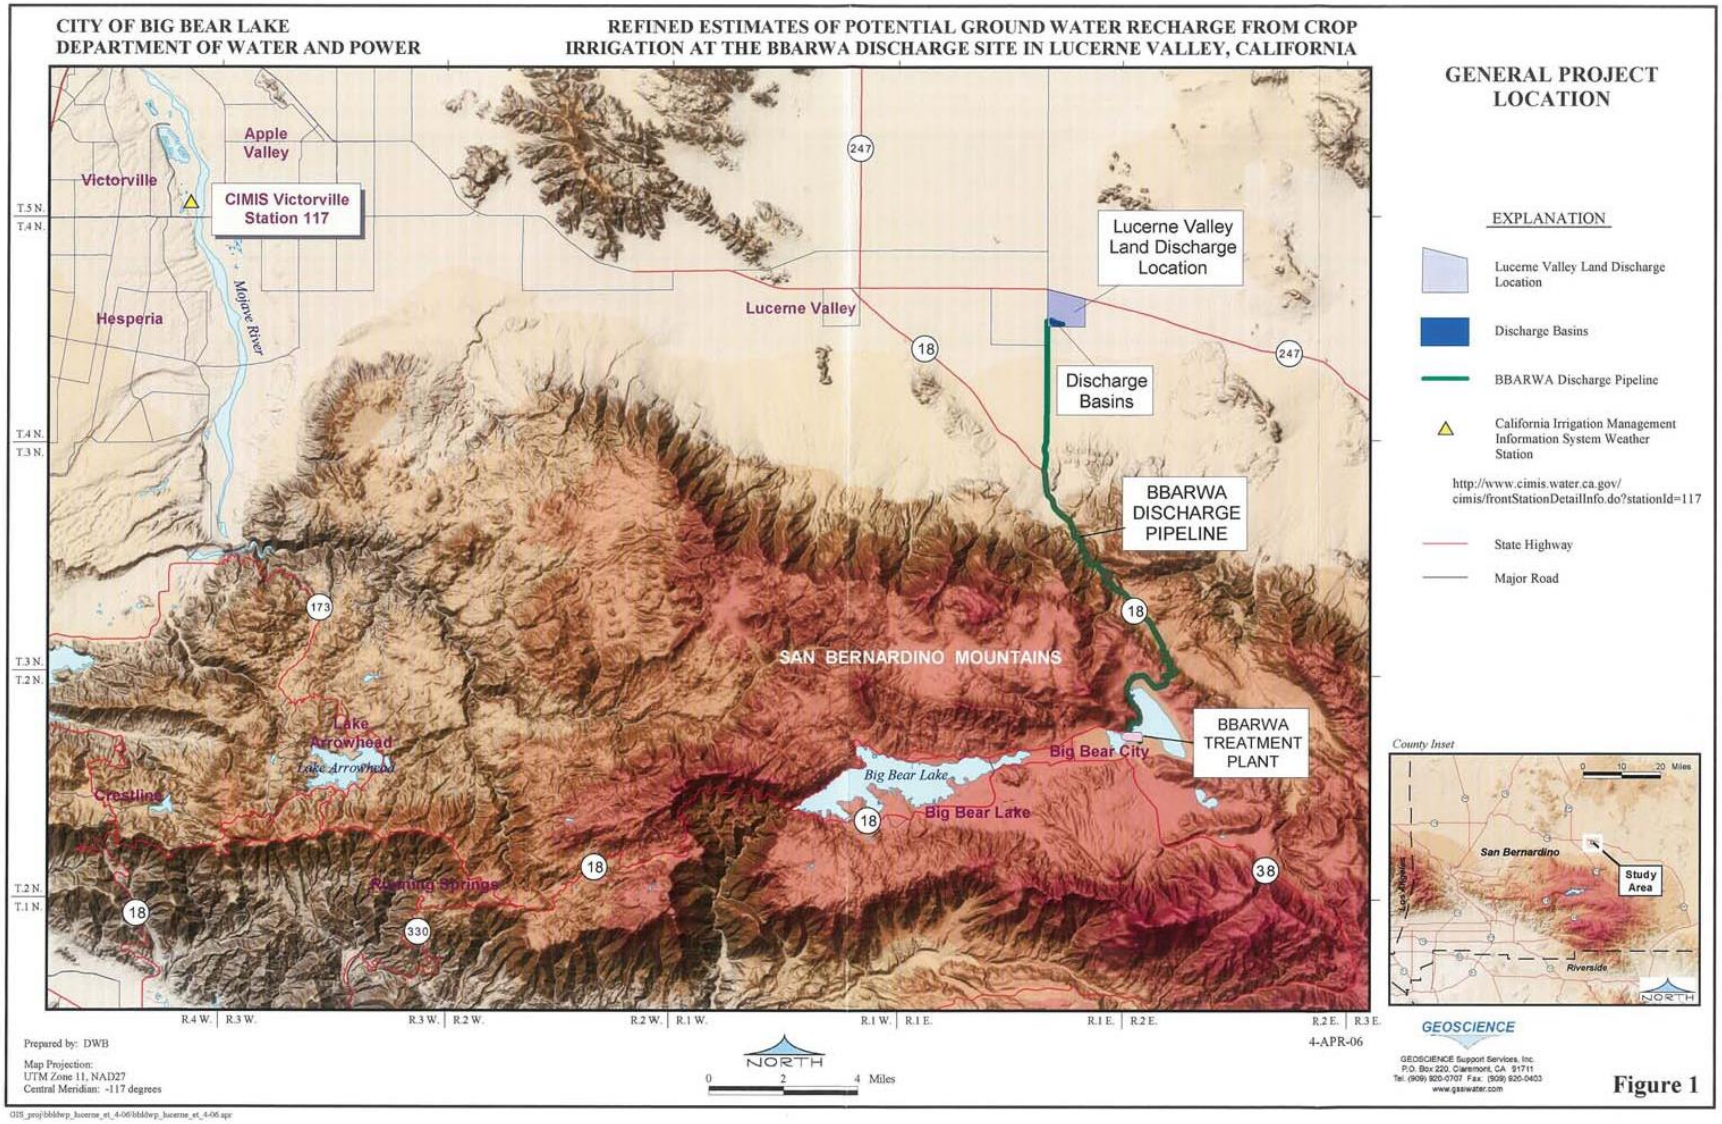

Figure 1: Location of Lucerne Valley Irrigation Site (1)

Figure 2: Warning Signs at Lucerne Valley Facility

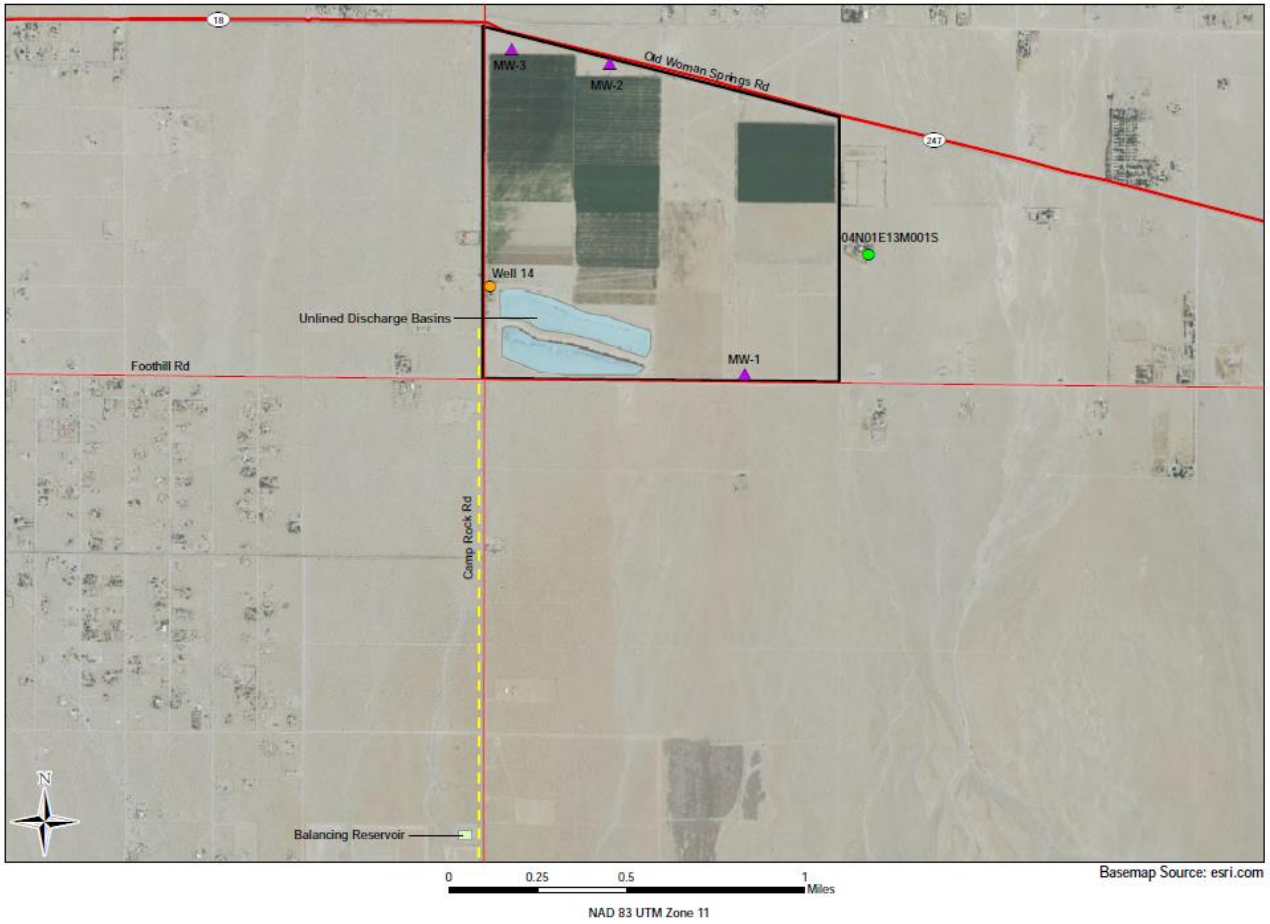

Figure 3: Site Layout and Well Locations (2)

2.2 FARMING OPERATION

The information presented in this section was obtained during a site visit and interview with the farmer and BBARWA staff conducted on September 6, 2016.

The Lucerne Valley Facility has been in operation as a farm since 1980 and is operated by a farmer who leases the land from BBARWA. Alfalfa and a grain mixture consisting of barley, oat and wheat are grown onsite and sold as feed for animals not producing milk for human consumption. Historically, up to 330 acres of the site has been farmed; however, the farmed area was reduced in 2012 to only 190 acres due to reduced water availability associated with drought conditions. The current farmed area remains at 190 acres with no plans to increase the acreage.

2.3 RECYCLED WATER DISTRIBUTION

The recycled water from the BBARWA WWTP flows to a concrete balancing reservoir along Camp Rock Road, shown in Figure 3, then by gravity to the Lucerne Valley Facility. At the Lucerne Valley Facility, the water can be directed to three locations: the West Fields, the East Fields, or the unlined discharge basin (Earth Basin). Two water meters located in the distribution system record flows to both the West and East Fields. Flow to the Earth Basin can be calculated by subtracting the sum of the metered flows to the West and East Fields from the total effluent flow leaving the BBARWA WWTP. The WWTP and field meters are calibrated annually by BBARWA.

During the summer months, all of the water is typically applied to the fields and little to none goes to the Earth Basin. In winter months, and on some other occasions, some or all of the water is routed to the Earth Basins for disposal. This is typically the result of one of the following:

- The recycled water flow is in excess of the crop needs. This occurs primarily in the winter when wastewater flows may be higher than average and crop water demands are lower.
- The concrete balancing reservoir is being drained for inspection or maintenance.
- An herbicide was applied at the BBARWA WWTP near the effluent storage ponds. Flow is diverted from the crops for a day or two to ensure that they are not impacted by the herbicide.

The amount of water applied to the fields and the Earth Basin each month is presented in the Water Balance in Section 4.

2.4 FARMING PRACTICES

Crop rotation is practiced on the farm at the Lucerne Valley Facility. Alfalfa is the primary crop grown on a 5-year cycle. Every five years, the alfalfa is replaced by a grain mixture of barley, oat and wheat to ensure healthy, nutrient-rich soil. This grain mixture is typically planted in late November, typically on a 50-acre portion of the farm at a time. The remaining fields continue to grow alfalfa. When planting crops, the farmer first disks the ground to prepare the soil, irrigates the prepared soil, then disks the ground again before planting the seed for the new crop.

2.4.1 Irrigation Practices

Irrigation is applied via a sprinkler system onsite as determined by the farmer; no automatic irrigation controller is used during the process. Irrigation is performed in sets that vary by the crop being irrigated. Each set covers a section that is approximately 100 ft by ¼ mile, or about 3 acres. The irrigation guidelines the farmer follows are detailed in Table 1. These durations are used throughout the entire year.

Table 1: Typical Irrigation Schedule

Description	Area Irrigated	Duration
Alfalfa	3 Acres	12 Hour Set
Reseeded Area	3 Acres	4 Hour Set
Grain Mixture	3 Acres	6 Hour Set

Precautionary measures are taken to ensure that the irrigation water is maintained onsite. The site is graded to prevent ponding and irrigation runoff from leaving the site. Any irrigation water that turns into runoff flows north to a ditch that is designed to contain the water on the property. Irrigation overspray leaving the property is prevented whenever possible. When the wind is blowing, the sprinkler heads located adjacent to the road are plugged in an effort to prevent the wind from carrying the irrigation water offsite.

2.4.2 Fertilizer Additions

When needed, fertilizer is typically applied with a loading of 100 pounds nitrogen/acre in the form of urea. Fertilizer is usually applied when switching from grain to alfalfa, but is not needed between rounds of alfalfa. Typically, fertilizer is applied on a three-year cycle that corresponds with the crop rotation schedule. However, the last fertilizer application occurred in April 2014, in which 70 acres of crops were fertilized. Available historical fertilizer information can be found in the nitrogen balance, attached as Appendix B.

The farmer's judgement is executed when deciding whether or not to apply the fertilizer. Soil samples were collected in 1999 to determine whether the alfalfa crops were getting the required nutrients, however no such samples have been taken since this 1999 study and the results of this study are unavailable. The farmer bases his decision on the look and feel of the crops. When the crops look yellow, additional fertilizer is added.

2.5 SOIL CHARACTERISTICS

Geophysical and lithologic logs from drilling the monitoring wells at the Lucerne Valley Facility indicate that the soil is composed of reddish brown sand, gravel and silt for the first 140 feet. Layers of unconsolidated sands, gravels, silts and clays extend to a depth of 255 feet below the Lucerne Valley Facility. An excerpt of the geologic profile is provided as Appendix A.

2.6 CLIMATIC CONDITIONS

The climatic conditions for the Lucerne Valley Region were determined using California Irrigation Management Information Systems (CIMIS) data for the Victorville Station (Station 117) and are summarized in Table 2. According to the Mojave Water Agency's 2015 Urban Water Management Plan, Victorville is representative of the regional climate for the surrounding region. However, the Lucerne Valley can be drier, windier and have greater temperature variability than is seen within the city of Victorville (3).

Table 2: Climate Data for the Lucerne Valley Region

Station	Total ET_o (in)	Total Precipitation (in)	Avg Max. Air Temp. (F)	Avg Min. Air Temp (F)	Avg Air Temp. (F)	Avg Wind Speed (mph)
1997	68.4	6.4	74.7	45.9	61.4	6.3

3 BBARWA EFFLUENT CHARACTERISTICS

3.1 EFFLUENT FLOW

BBARWA treats the wastewater of all of its Member Agencies. Following preliminary and secondary treatment, 100% of the effluent flow, including the winter peaks, is delivered to the Lucerne Valley Facility via the pipeline shown in Figure 1. The historic effluent flows beginning in the year 2005 are shown in Figure 4. Note that flows to the Lucerne Valley Facility dropped considerably after 2012 due to drought conditions and have remained lower except for larger rainstorms in 2017 and 2019. Flows increased in 2020 due to a sustained influx of visitors during the COVID-19 pandemic, but are expected to return to previous levels.

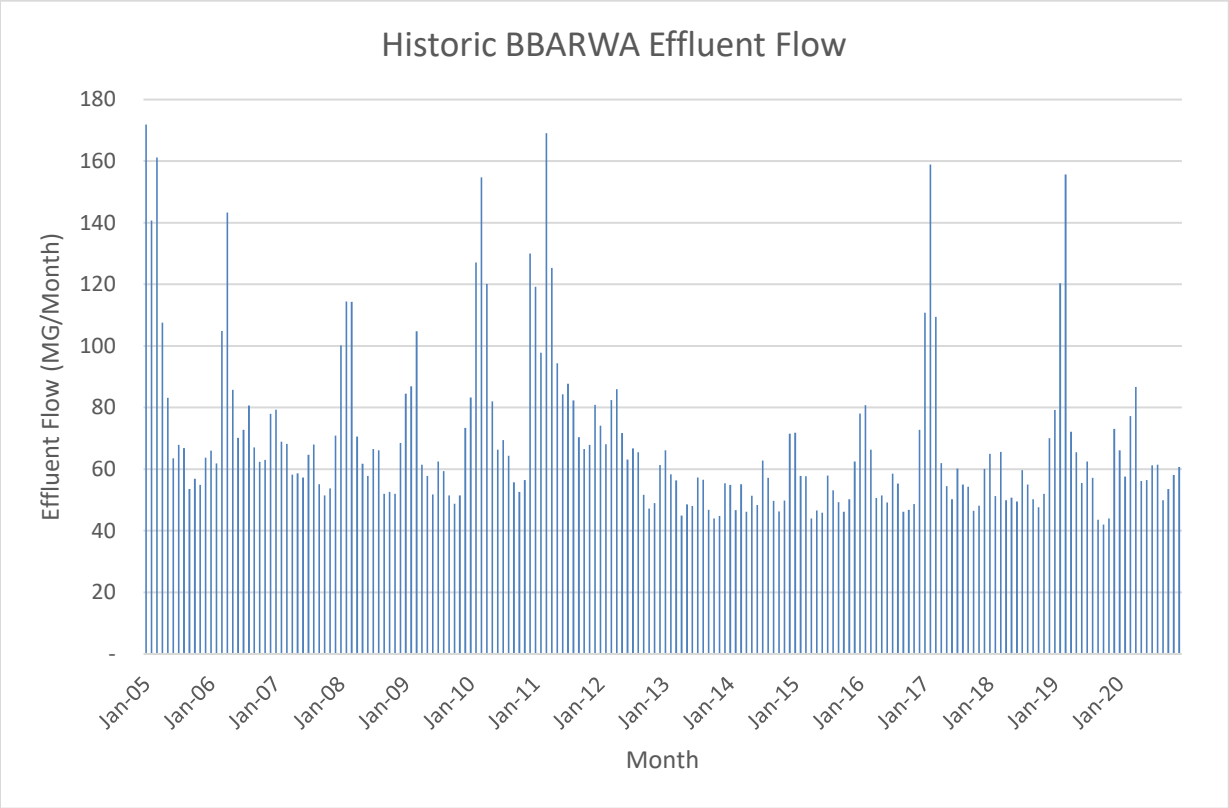

Figure 4: Historic Effluent Flow

3.2 EFFLUENT WATER QUALITY

BBARWA's effluent water quality delivered to the Lucerne Valley Facility is regulated by the Colorado River Region WDR. The quality of the water sent to the Lucerne Valley Facility is generally good and has not historically posed a threat to any of the crops. The farmer reports that the current irrigation practices have not resulted in salt buildup within the soil.

Constituents of concern specified in Colorado River Region WDR include nitrogen and TDS. Historic concentrations for each of these constituents are presented in Figure 5. Concentrations vary widely but have been in compliance historically. There are no planned process changes at the BBARWA WWTP that would impact future nitrogen and TDS concentrations. Despite lower flows in recent years due to drought conditions, the WWTP has successfully achieved nitrogen and TDS effluent compliance.

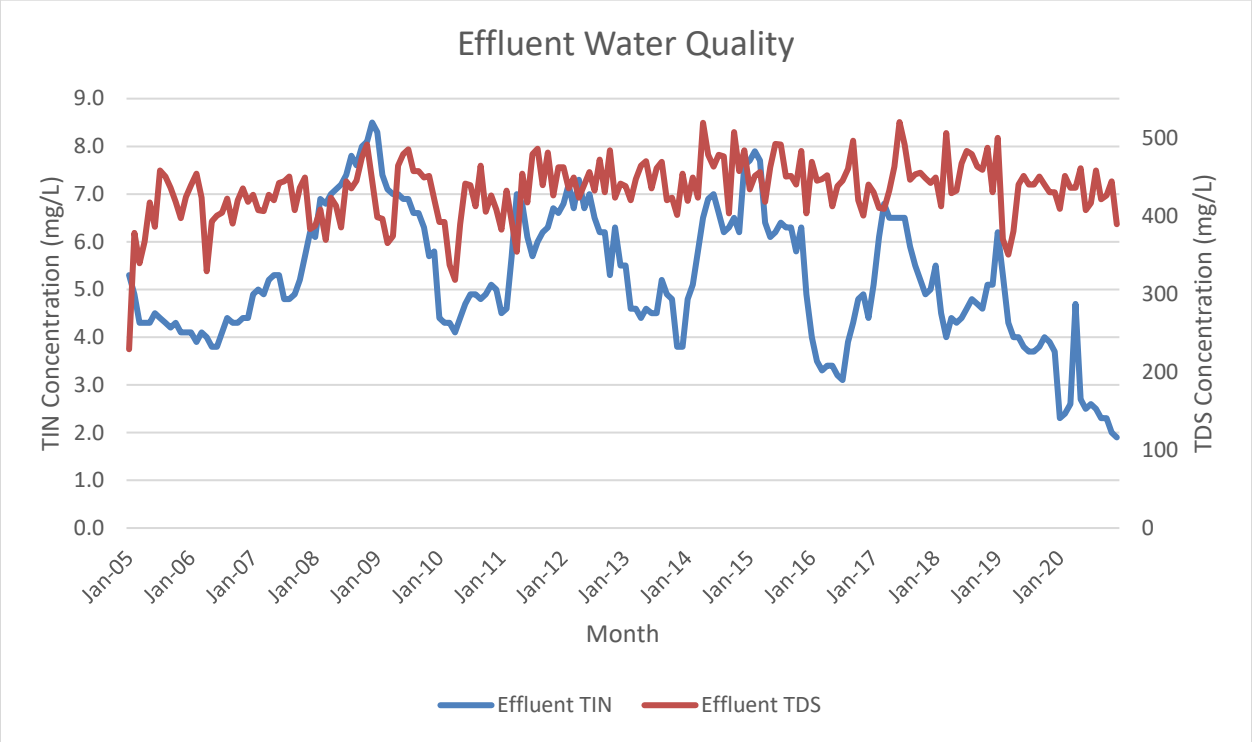

Figure 5: BBARWA Effluent Quality

3.3 SUMMARY OF DISCHARGE PERMIT COMPLIANCE

The effluent limitations specified in the Colorado River Region WDR for the earth basins are outlined in Table 3. During the study period for this report, which spans years 2005-2020, BBARWA's treated effluent discharged to the Lucerne Valley Facility has historically been in compliance with the Colorado River Basin WDR in effect at that time.

Note that an effluent limit for TDS is not included in the current Colorado River Basin WDR. Special Provision No. 1 of the WDR requires BBARWA to conduct a study of the groundwater in the vicinity of the Lucerne Valley Facility and propose an appropriate effluent limit for TDS. That study was completed on December 22, 2017 by Thomas Harder & Co. Groundwater Consulting.

Table 3: WDR Effluent Limitations

Constituent	Units	30-Day Arithmetic Mean	7-Day Arithmetic Mean	Daily Maximum
20°C BOD_5	mg/L	30	45	-
Total Suspended Solids	mg/L	30	45	-
Chloride	mg/L	60	-	80
Sulfate	mg/L	60	-	80
Boron	mg/L	-	-	0.75
Total Nitrogen	mg/L	10	-	-
Average Daily Dry Weather Flow	MGD	4.8	-	-
pH	Unitless	6.0 ≤ pH ≤ 9.0		

As part of Finding 11 of the Colorado River Region WDR, BBARWA must comply with Title 22 CCR Section 60304(d)(4) for irrigating with undisinfected secondary recycled water. BBARWA received approval for their Title 22 Engineering Report on November 3, 1980. Finding 12 of the WDR specifies the conditions under which sheep can graze at the irrigation site. While sheep have grazed on site in the past, there are no longer sheep grazing on site. During the last site visit by Colorado River Basin RWQCB Staff on June 13, 2016, the fence around the Lucerne Valley Facility was found to be damaged due to a tear resulting from an auto accident. This tear has since been repaired as directed by RWQCB staff.

4 WATER AND NITROGEN BALANCE

4.1 CROP IRRIGATION REQUIREMENTS

Crop irrigation requirements were estimated using evapotranspiration (ET_o) data gathered from the California Irrigation Management Information System (CIMIS) Station 117 in Victorville, CA, which is based on grass as the reference crop. Crop specific demand was estimated using Equation 1, where K_c is a seasonal crop coefficient specific to each crop. This K_c value was determined using the FAO Grass-Based Crop Coefficients method outlined in *ASCE Manual No. 70: Evaporation, Evapotranspiration, and Irrigation Water Requirements* (4). Under this methodology, there are four distinct growing periods in each growing cycle: the initial, crop development, midseason, and late season periods. There are three distinct crop coefficients (initial, middle, and end) that are used in tandem with these growing periods to develop a crop coefficient curve. To obtain reference crop coefficients applicable to the climate at the Lucerne Valley Facility, values from the ASCE Manual must be adjusted using the relative humidity and wind speed for the irrigation area. Using the corrected values and the crop coefficient curves (attached as Appendix C), a monthly crop coefficient value can be estimated for each crop. The calculated values for each crop for each month are tabulated in the Water and Nitrogen Balance in Appendix B.

$$ET_c = K_c * ET_o$$

Equation 1: Crop Specific Evapotranspiration Rate

4.1.1 Alfalfa

Alfalfa crop coefficients were determined using *ASCE Manual No. 70*. Based on the data provided in the manual, Alfalfa has two types of growing cycles – the initial cutting cycle and all other cycles. The initial cutting cycle typically lasts 60 days and all other subsequent cycles last 30 days according to *ASCE Manual No. 70* (4). However, the farmer typically performs five to six harvests a year. For the purposes of this report, six alfalfa harvests per year were used with cutting cycles of 60 days each to align with this timeline. The irrigation demand for the crop varies by growing stage due to differing K_c values and varying rainfall but ranges from 1.3 to 8.7 inches of water/acre of alfalfa. This is discussed further in Section 4.1.3.

4.1.2 Grain Blend – Barley, Wheat, Oat

The grain blend crop coefficient was also determined using *ASCE Manual No. 70*. Crop coefficients for barley, wheat and oat were all estimated using the initial period, crop development period, midseason period, and late season period and the initial, middle, and end reference crop coefficients. These coefficients were then averaged over the three crops and corrected for relative humidity and wind speed to provide an estimate for the grain blend crop coefficient. The farmer performs one grain harvest per year and harvests the crop after 90 days, so 90 days was used for the cutting cycle duration. The irrigation demand for the grain blend varies by stage due to the seasonal nature of K_c and varying rainfall, but ranges from 0 to 12.0 inches of water/acre of grain. This is discussed further in Section 4.1.3.

4.1.3 Historic Irrigation at Lucerne Valley Facility

A water balance was developed for the years 2005 to 2020 to determine whether irrigation water is being applied at appropriate rates. BBARWA maintains flow meters that log the amount of irrigation water being applied to the West and East Fields, however the meters have not been functional for many years. New meters for these fields were installed, calibrated, and connected to BBARWA's SCADA system in April 2021 and should provide more accurate data for effluent flow distribution to the fields and earth basin. When meter data for the fields was unavailable, BBARWA maintained daily log books to note whether the effluent was directed to the Earth Basin or to the fields each day (flow is not split between the basin or fields on a daily basis). The WWTP effluent meter flow data was then used to total monthly flows to the Earth Basin and the fields. Flow to each field was allocated in accordance with each field's area relative to the total field area (West Field plus East Field).

Evapotranspiration data from CIMIS Station 117 was used with the estimated crop coefficients (discussed in Section 4.1) to determine total crop water demand and rainfall supplied. Irrigation water and rainfall were summed to obtain the total water applied to the crops. Any water applied above crop demand, whether wastewater effluent or rain water, is regarded as excess irrigation. The excess irrigation for the Lucerne Valley Facility is plotted in Figure 6 and tabulated in Appendix B.

Based on the ET_c water demand methodology discussed in Section 4.1, the historical irrigation analysis indicates that the farmer often over-waters the crops at the Lucerne Valley Facility, particularly during the winter months, in which rainfall is more prevalent. For the purposes of this water balance, it was assumed that 315 acres was farmed through the year 2011. At this point, drought conditions had reduced available recycled water supply resulting in the farmer reducing the farmed acreage to 190 acres in the year 2012. The farmed acreage has remained at 190 acres since the year 2012.

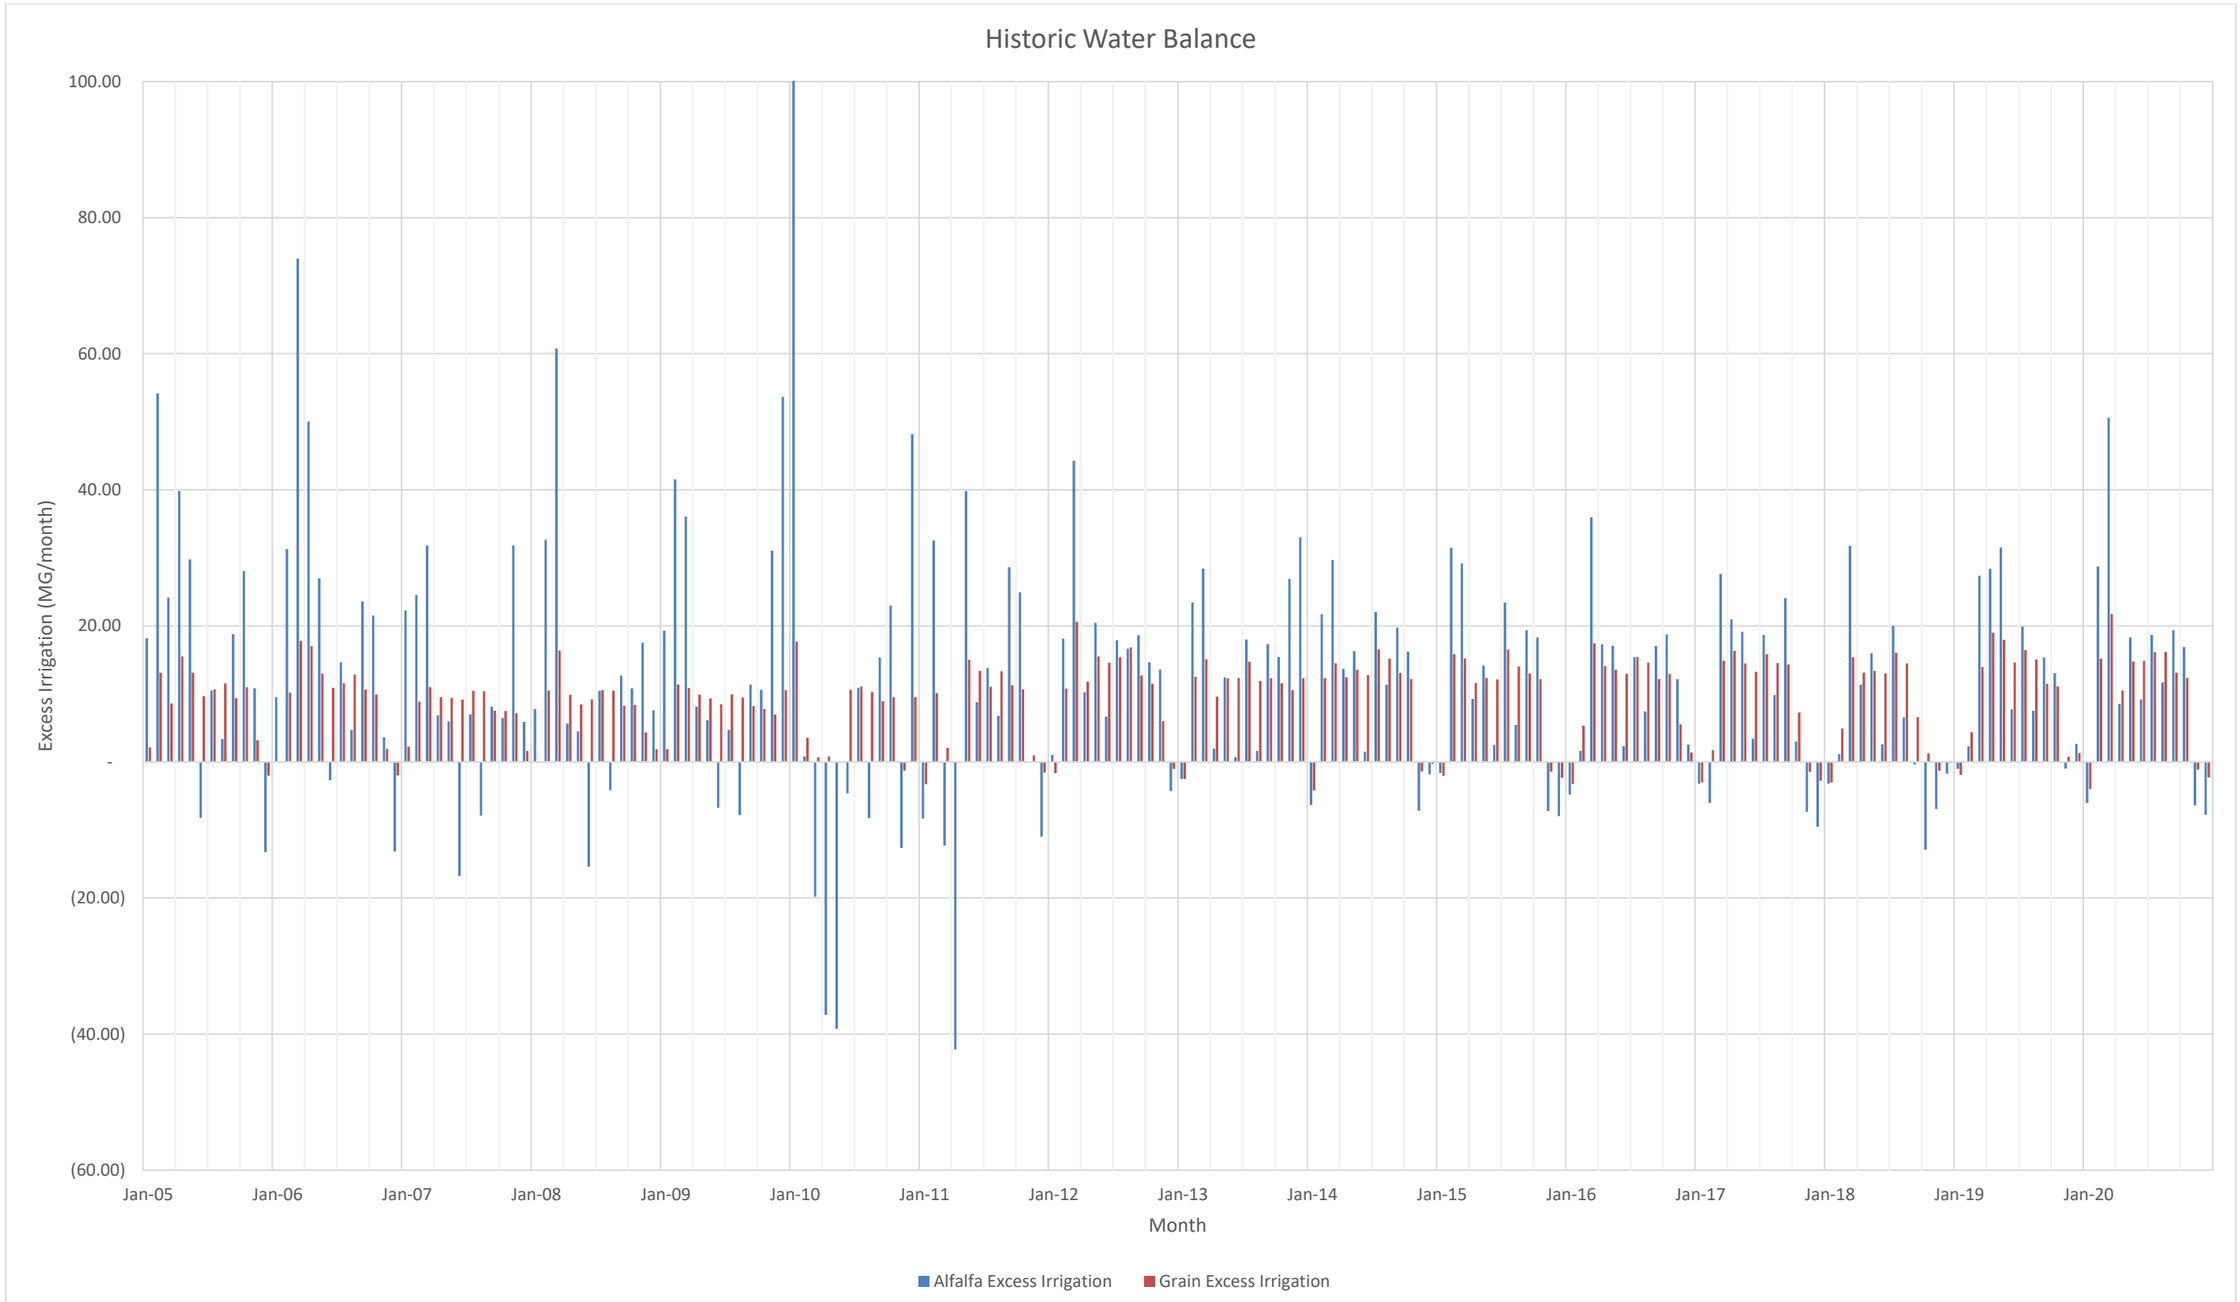

Figure 6. Historic Irrigation at the Lucerne Valley Facility

4.2 CROP NUTRIENT REQUIREMENTS – NITROGEN

4.2.1 Alfalfa

Alfalfa can supply 70-90% of its nitrogen requirements through a symbiotic relationship with nitrogen-fixing Rhizobium bacteria that grow on its roots. These bacteria are able to fix N_2 gas found in air into a form that the alfalfa is able to use. However, alfalfa will preferentially use nitrogen in the soil over nitrogen that can be fixed from the air. If the alfalfa consumes all of the nitrogen content from within the soil, it will resume the nitrogen fixation process to meet its nitrogen needs. (5)

As alfalfa can supply most of the nitrogen it needs, nitrogen requirements for alfalfa crops are not typically specified and fertilizer is not typically needed. However, alfalfa does have the capacity to remove nitrogen from the soil and irrigation water. For this Plan, the nitrogen removal capacity of alfalfa was estimated using the International Plant Nutrition Institute's (IPNI) calculator, which estimates nitrogen removal based on estimated crop yield in tons per acre. The farmer estimates the average yield for alfalfa at the Lucerne Valley Facility is 1 ton per acre. This value was used with the IPNI calculator to determine a nitrogen removal capacity of 51 lb/acre per crop cycle. According to the farmer, there are 6 complete cutting cycles throughout the year for alfalfa. For the purposes of this report, average monthly nitrogen removal capacity was estimated by multiplying the removal per cycle by the number of cycles and then dividing by 12 months. This results in an average alfalfa nitrogen removal capacity of 25.5 lb/acre per month. However, complete nitrogen removal capacity may not always be achieved. According to a UC Davis study, alfalfa will still fix 10-25% of its nitrogen from the air, even when the applied nitrogen concentrations are high (5). To minimize nitrogen leaching, it is recommended that nitrogen be applied at a rate that does not exceed 75-85% of the nitrogen removed in the harvest. This Plan uses an estimated nitrogen removal capacity for alfalfa of 75% of the 25.5 lb/acre per month, or 19.13 lb/acre per month.

For the purposes of this Plan, the average annual nitrogen uptake is used to calculate a constant monthly nitrogen removal capacity. Actual nitrogen uptake by the crops varies by growth stage.

The historic nitrogen loadings applied to the alfalfa crop at the Lucerne Valley Facility is presented in Section 4.2.3.

4.2.2 Grain blend – barley, wheat, oat

Barley, wheat and oat all have differing nitrogen removal capacities. In order to estimate the grain blend's nitrogen removal capacity, the grain blend was assumed to be equal parts barley, wheat and oat, and their individual nitrogen removals were averaged. Based on information from the farmer, each grain harvest yields 2.5 tons per acre, which equates to 84.2 bushels per acre. Nitrogen removal for each crop was estimated using IPNI's calculator for an 84.2 bushels per acre yield crop cycle.

- Barley has an expected nitrogen removal capacity of 83.3 lb N/acre per crop cycle.
- Winter wheat has an expected nitrogen removal capacity of 97.6 lb/acre per crop cycle.
- Oat yield has an expected nitrogen removal capacity of 64.8 lb/acre per crop cycle.

These nitrogen removal capacities were averaged, resulting in an estimated nitrogen removal capacity of 81.9 lb/acre per cycle. With one crop cycle occurring over 90 days, this demand was divided by 3 months to produce an estimated average nitrogen removal capacity of 27.3 lb/acre per month.

For the purposes of this Plan, the average annual nitrogen uptake is used to calculate a constant monthly nitrogen removal capacity. Actual nitrogen uptake by the crops varies by growth stage.

4.2.3 Nitrogen Application and Removal Capacity

A nitrogen balance was constructed for the years 2005 to 2020 for the Lucerne Valley Facility, which focuses on the nitrogen uptake of the alfalfa and grain mixture. The nitrogen content of the BBARWA effluent in the form of Total Inorganic Nitrogen (TIN) was used to estimate the quantity of nitrogen applied to the crops each month. This value was combined with the nitrogen content of any fertilizer applied to the crops and compared with the average crop nitrogen removal capacity presented in Section 4.2 to determine if the crop is receiving more nitrogen than it can remove. The total nitrogen application is compared with the nitrogen removal capacity and is plotted in Figure 7, which shows that the nitrogen removal capacity of the crops at the Lucerne Valley Facility generally exceeds the nitrogen applied to the crops. There are a few instances where higher than average effluent flows (2017) or fertilizer application (2014) result in the nitrogen applied exceeding the nitrogen capacity of the crops. However, in most of these instances, the removal capacity is only slightly less than the applied nitrogen. The crop's nitrogen removal capacity has been significantly greater than the nitrogen applied in recent years, indicating the farmer has made appropriate adjustments to his irrigation practices. BBARWA will continue to monitor the quantity of effluent applied relative to the crop removal capacity and coordinate with the farmer if adjustments need to be made to maintain balance.

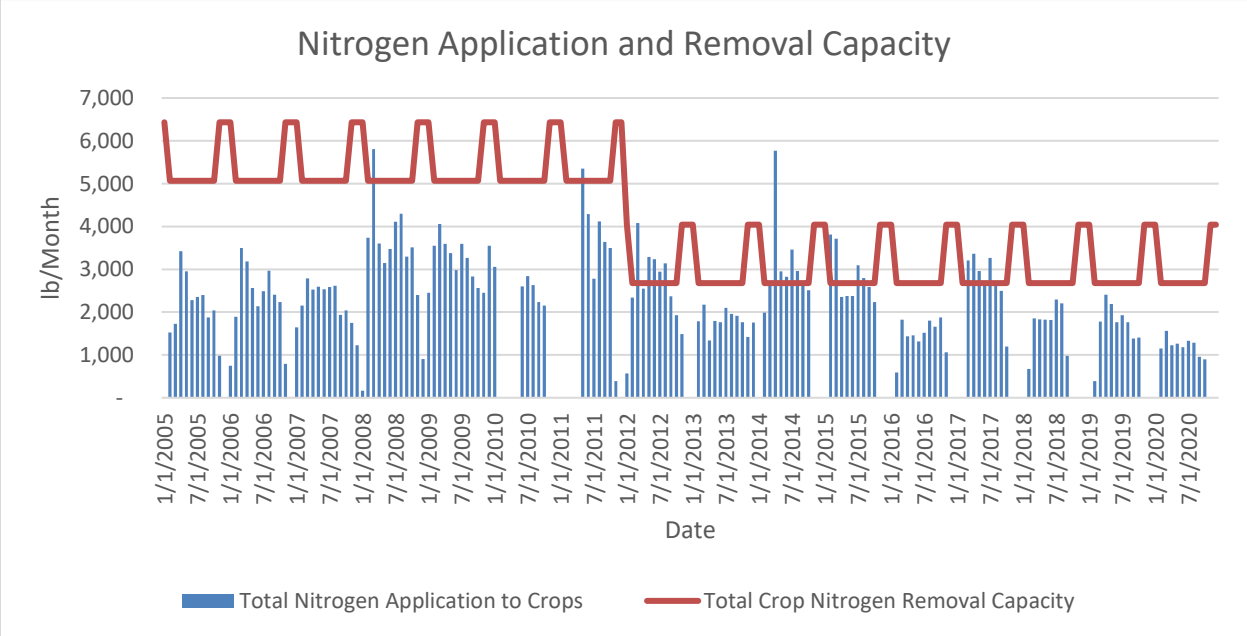

Figure 7: Nitrogen Application and Removal Capacity

5 CONCLUSIONS & RECOMMENDATIONS

The water and nutrient balance analyses indicate that the farmer is managing nutrient application at the Lucerne Valley Facility appropriately and that irrigation water in excess of the minimum crop requirement is often applied.

Based on the water balance conducted for alfalfa and grain (as shown in Figure 6), crops at the Lucerne Valley Facility often receive irrigation water in excess of the minimum crop requirements, particularly in the winter months where rainfall influences this value. In most of these instances, the rainfall provides more water than the crops need, so over-watering occurs even without application of effluent. It can be conservatively assumed that any applied irrigation water not required by the crop will percolate into the underlying groundwater. This incidental percolation is considered in the groundwater quality evaluation conducted by Thomas Harder & Co., as discussed in Section 3.3. In more recent years, the drought has limited irrigation water availability for the Lucerne Valley Facility and has forced the farmer to reduce the irrigated acreage at the site. This has also resulted in reduced occurrences of over-watering.

The nutrient balance for the alfalfa and grain mixture (as shown in Figure 7 and Appendix B) indicates that the crops planted at the Lucerne Valley Facility generally have the capacity to remove more nitrogen than is applied through the effluent and fertilizer, although actual removal rates will vary depending on crop growth cycles. BBARWA will continue to monitor the quantity of effluent applied relative to the crop removal capacity and coordinate with the farmer if adjustments need to be made to maintain a nutrient balance.

This report is intended to meet the requirement to perform an annual water and nutrient balance through 2020.

Notes:

1. From effluent meter located at the BBARWA Wastewater Treatment Plant.
2. Data prior to 2016 is from the west field meter at the Lucerne Valley Site unless otherwise noted in the "Notes" column. For 2016 - 2020, field flow was estimated in accordance to the size of each field (60 acres in the east field and 130 acres in the west field).
3. Data prior to 2016 is from the east field meter at the Lucerne Valley Site unless otherwise noted in the "Notes" column. For 2016-2020, field flow was estimated in accordance with the size of each field (60 acres in the east field and 130 acres in the west field).
4. Estimated Effluent to Earth Basin = Earth Basin Estimates from BBARWA - West Field Flow - East Field Flow. The sum of the field meter readings is typically lower than the effluent flow meter reading when no flow is being sent to the pond. BBARWA considers this to be caused my compound meter tolerances, but the results produce conservative estimates of the volume of water sent to the Earth Basin.
5. ETo is the reference evapotranspiration. This data is provided as part of the CIMIS data set for Station 117. Source: CIMIS (http://www.cimis.water.ca.gov/)
6. Rainfall data is provided as part of the CIMIS data set for Station 117. Source: CIMIS (http://www.cimis.water.ca.gov/)
7. K_c is the crop characteristics coefficient. This coefficient is seasonally based as it depends on the growth stage for the crop. Methodology follows the Food and Agriculture Organization of the United Nations' (FAO) Grass-Based Crop Coefficients method outlined in ASCE Manuals and Reports on Engineering Practice #70: Evaporation, Evapotranspiration, and Irrigation Water Requirements by Marvin Jensen, Ph.D., NAE and Richard Allen, Ph.D., PE. Calculations for these can be found on the "Alfalfa Kc" and "Grain Kc" tabs repectively.
8. ET_c is the crop evapotranspiration for the specific crop under standard conditions. It represents the water demand for the specific crop during that time period. It is determined using the following formula:
   $ET_c = K_c * ETo$, where K_c is the crop characteristics coefficient. Source: FAO (http://www.fao.org/docrep/x0490e/x0490e0b.htm)
9. Effluent Depth on Total Acreage = (Total Flow to Fields * 1,000,000 gal/MG * 0.1337 ft^3/gal * 12 in/ft)/(Total Planted Acreage * 43,560 ft^2/acre)
10. Total Water Depth on Acreage = Effluent Depth on Total Acreage + Rainfall
11. Alfalfa Surplus or Deficit = [(Total Water Depth on Acreage - ET_c alfalfa) * Alfalfa Acreage * 43,560 ft^2/acre]/(12 in/ft * 0.1337ft^3/gal * 1,000,000 gal/MG)
12. Grain Surplus or Deficit = [(Total Water Depth on Acreage - ET_c grain) * Grain Acreage * 43,560 ft^2/acre]/(12 in/ft * 0.1337ft^3/gal * 1,000,000 gal/MG)
13. Combined Surplus or Deficit = Alfalfa Surplus or Deficit + Grain Surplus or Deficit
14. Effluent Total Inorganic Nitrogen (TIN). Calculated using a flow weighted average. Source: (BBARWA Annual Reports)
15. TIN Loadings to Fields = [Calculated Flow to Fields * 1,000,000 gal/MG * 3.78541 L/gal * Effluent TIN mg/L]/[1,000 mg/g * 453.592 g/lb]
16. TIN Loadings to Ponds = [Calculated Flow to Earth Basin * 1,000,000 gal/MG * 3.78541 L/gal * Effluent TIN mg/L]/[1,000 mg/g * 453.592 g/lb]
17. Alfalfa Nitrogen Removal Capacity was determined using a yield of 1 ton/acre per harvest (Source: BBARWA farmer) with the International Plant Nutrition Institute's (IPNI) crop nutrient calculator ((Source: https://www.ipni.net/ipniweb/app/calc.nsf/0/0962F87B1D2E67718525808C00025B0C). This output is on a per harvest basis, so the number was multiplied by the number of cuttings (6 per the farmer) and then divided by 12 months to determine a monthly value. Additional information can be found on the "Nutrient Requirements" tab.
18. Grain Nitrogen Removal Capacity was determined based on the BBARWA farmer's reported output of 2.5 tons per acre for the grain mixture, which equates to a yield of 84.2 bushels per acre. For the purposes of the estimate, it was assumed that the mixture has equal yields among the barley, winter wheat, and oats. The IPNI calculator was used to estimate nitrogen uptake for each type of grain. The IPNI outputs were calculated for each grain's proportional yield and summed to get an average grain uptake , multiplied by the number of harvests (one per year), and then divided by 3 months (harvest cycle) to provide a monthly estimate. Additional information is found under the "Nutrient Requirements Tab."
19. Alfalfa Nitrogen Removal Capacity (lbs) = Alfalfa Nitrogen Removal Capacity (lb/acre) * Alfalfa Acreage (acres)
20. Grain Nitrogen Removal Capacity (lbs) = Grain Nitrogen Removal Capacity (lb/acre) * Grain Acreage (acres)
21. Total Nitrogen Removal Capacity (lb) = Alfalfa Nitrogen Removal Capacity (lb) + Grain Nitrogen Removal Capacity (lb)

Bear Valley Basin Groundwater Sustainability Plan

January 2022

Prepared for

Bear Valley Basin Groundwater Sustainability Agency

Prepared by

Table of Contents

1. Introduction to the Bear Valley Basin Groundwater Sustainability Plan 1
1.1 Purpose of the Sustainable Groundwater Management Act 1
1.2 Description of the Bear Valley Groundwater Basin 1
1.3 Basin Prioritization 2
1.4 Agency Information 4
1.4.1 Agencies Names and Mailing Addresses 4
1.4.2 Agency Organization and Management Structure 5
2. Bear Valley Basin Setting 6
2.1 Hydrogeologic Conceptual Model 6
2.1.1. Sources of Data 6
2.1.2. Geologic Setting 7
2.1.3. Lateral Basin Boundaries 9
2.1.4. Bottom of Basin 9
2.1.5. Surface Water Features 10
2.1.5.1 Big Bear Lake 10
2.1.5.2 Baldwin Lake 10
2.1.5.3 Lake Erwin 11
2.1.5.4 Springs 11
2.2 Areas of Groundwater Recharge and Discharge 12
2.2.1 Recharge 12
2.2.2 Discharge 12
2.3 Principal Aquifer and Aquitards 13
2.3.1 Aquifer Formations 13
2.3.2 Aquifer Physical Properties 14
2.3.3 Geologic Structures that Affect Groundwater Flow 16
2.3.4 Aquifer Water Quality 16
2.3.5 Aquifer Primary Uses 17
2.4 Uncertainty in the Hydrogeologic Conceptual Model 17
2.5 Groundwater Conditions 17
2.5.1 Groundwater Occurrence and Flow 17

2.5.2 Groundwater Storage 21
2.5.3 Seawater Intrusion 21
2.5.4 Groundwater Quality Issues 22
2.5.5 Land Subsidence 22
2.5.6 Interconnected Surface Water Systems 22
2.5.7 Groundwater Dependent Ecosystems 23
2.6 Water Budget 23
2.6.1 Surface Water Budget 23
2.6.1.1 Surface Water Inflow 24
Precipitation 24
Natural Lake Inflow 25
Water Supply from Wells 25
Spring Flow 25
2.6.1.2 Surface Water Outflow 26
2.6.2 Groundwater Budget 28
2.6.2.1 Sources of Groundwater Recharge 28
2.6.2.2 Sources of Groundwater Discharge 29
2.6.3 Changes in Groundwater Storage 30
2.6.4 Overdraft 30
2.6.5 Water Year Type 30
2.6.6 Sustainable Yield 30
2.6.7 Current Water Budget 32
2.6.8 Historical Water Budget 32
2.6.9 Projected Water Budget 33
2.7 Management Areas 34
2.7.1 Criteria for Management Areas 34
2.7.2 Monitoring Plan 37
2.7.3 Coordination with Adjacent Areas 38
3. Sustainable Management Criteria 39

1. Introduction to the Bear Valley Basin Groundwater Sustainability Plan

1.1 Purpose of the Sustainable Groundwater Management Act

In September 2014, the Sustainable Groundwater Management Act (SGMA) was signed into law, with an effective date of January 1, 2015, and codified in the California Water Code, Section 10720 et seq. The legislative intent of SGMA is to, among other goals, provide for sustainable management of alluvial groundwater basins and subbasins defined by the California Department of Water Resources (CDWR), to enhance local management of groundwater, to establish minimum standards for sustainable groundwater management, and to provide specified local agencies with the Agency and the technical and financial assistance necessary to sustainably manage groundwater. To comply with and satisfy the requirements of SGMA, the following activities are mandated:

- Formation of a Groundwater Sustainability Agency (GSA) by June 30, 2017.
- Development of a Groundwater Sustainability Plan (GSP) by January 31, 2022.
- Implementation of the GSP to achieve quantifiable objectives and sustainability within 20 years (by 2042).
- Annual reporting of groundwater conditions in the basin to the CDWR.
- Periodic (every five years) evaluation of the GSP implementation by the GSA.

This document fulfills the GSP development requirement for the Bear Valley Basin. Specifically, the GSP provides the geographical and managerial context of the Bear Valley Basin, summarizes the groundwater basin setting (including groundwater conditions, water budget, and management areas), describes the criteria used to measure and demonstrate sustainability, reviews the existing groundwater monitoring and management programs, and defines how those actions will be incorporated into the Bear Valley Basin GSP to achieve and maintain sustainability in the future.

1.2 Description of the Bear Valley Groundwater Basin

This GSP covers the entire Bear Valley Groundwater Basin identified as Basin No. 8-009 in the CDWR Bulletin 118 (see Figure 1-1). The groundwater basin underlies the Big Bear Valley and covers approximately 30 square miles within the San Bernardino Mountains in southern San Bernardino County, California. The Big Bear Valley is an east-west trending valley that extends from Big Bear Lake Dam on the west to the eastern portion of Baldwin Lake on the east. The valley is surrounded by a series of local mountain ranges which rise to approximately 7,000 to 8,000 feet above sea level. Average annual precipitation ranges from approximately 35 inches on the western edge of the valley and in the mountains south of Baldwin Lake to 18 inches on the eastern edge of the valley (Flint and Martin, 2012). Big Bear Lake and Baldwin Lake are the

primary surface water features within the Bear Valley Groundwater Basin, and the basin is within the watershed areas of the Big Bear Lake and Baldwin Lake surface water drainage basins. These drainage basins are composed of multiple subbasins which are defined by surface water divides. The numerous creeks within these subbasins drain into Big Bear and Baldwin Lakes; the only significant surface water outflow from the valley is through Bear Valley Dam. Urban areas within the Bear Valley Groundwater Basin include the cities of Big Bear Lake, Fawnskin, Sugarloaf, and Big Bear City. Highways 18 and 38 are the primary driving routes within the valley.

The Bear Valley Basin is generally composed of alluvial deposits which are bound by pre-Tertiary crystalline (basement) rocks of the San Bernardino Mountains. Groundwater is produced from three primary geologic formations: unconsolidated or semi-consolidated alluvial sediments, fractures and weathered zones in granitic bedrock, and fractures and cavities in carbonate bedrock. Groundwater production wells that typically have the highest yields are constructed within the aquifers of the alluvial sediments. Currently, the entire municipal water supply in Big Bear Valley is from groundwater as there is no means of importing water into the area. The perennial yield (i.e. safe yield or sustainable yield) of the Bear Valley Basin has been estimated to be approximately 5,300 acre-feet/year. To date, annual groundwater production has never exceeded the perennial yield estimate and groundwater levels periodically recover to historical high conditions during wet periods. However, due to relatively limited aquifer storage in the basin, groundwater levels can vary widely between periods of relatively high precipitation and periods of low precipitation. As such, it is critical to monitor and manage groundwater levels to ensure adequate supplies during periods of prolonged drought. Since 2003, local agencies have implemented groundwater monitoring and management programs that have been successful at managing groundwater supplies to address periodic drought conditions, including the recent dry period between 2011 and 2017.

1.3 Basin Prioritization

CDWR's Bulletin 118 – Interim Update 2016 (CDWR, 2018) defined 515 groundwater basins and subbasins in California. CDWR is required to prioritize these groundwater basins and subbasins as "high," "medium," "low," or "very low" priority. The SGMA 2019 Basin Prioritization process was conducted to reassess the priority of the groundwater basins following the 2016 basin boundary modification, as required by the Water Code. For the SGMA 2019 Basin Prioritization, DWR followed the process and methods developed for the CASGEM 2014 Basin Prioritization, adjusted as required by SGMA and related legislation. CDWR is required to prioritize basins for the purposes of SGMA, which was enacted, among other things, to provide for the sustainable management of groundwater basins. This reprioritization entailed a reassessment of factors that had been utilized in the CASGEM program to prioritize basins based on groundwater elevation

monitoring. SGMA also required CDWR to continue to prioritize basins based on a consideration of the requirements specified in Water Code Section 10933(b):

1. The population overlying the basin or sub-basin.
2. The rate of current and projected growth of the population overlying the basin or sub-basin.
3. The number of public supply wells that draw from the basin or sub-basin.
4. The total number of wells that draw from the basin or sub-basin.
5. The irrigated acreage overlying the basin or sub-basin.
6. The degree to which persons overlying the basin or sub-basin rely on groundwater as their primary source of water.
7. Any documented impacts on the groundwater within the basin or sub-basin, including overdraft, subsidence, saline intrusion, and other water quality degradation.
8. Any other information determined to be relevant by the department, including adverse impacts on local habitat and local streamflow.

CDWR incorporated new data, to the extent data was available, and the amended the language of Water Code Section 10933(b)(8) (component 8) to include an analysis of adverse impacts on local habitat and local streamflow as part of the SGMA 2019 Basin Prioritization. Evaluation of groundwater basins at a statewide scale does not necessarily capture the local importance of groundwater resources within the smaller-size or lower-use groundwater basins. For many of California's low-use basins, groundwater provides close to 100 percent of the local beneficial uses. Thus, when reviewing the SGMA 2019 Basin Prioritization results, it is important to recognize the findings are not intended to characterize groundwater management practices or diminish the local importance of the smaller-size or lower-use groundwater basins; rather, the results are presented as a statewide assessment of the overall importance of groundwater resources in meeting beneficial uses.

The following information was deemed relevant and considered as part of component 8 for the SGMA 2019 Basin Prioritization based on SGMA:

- Adverse impacts on local habitat and local streamflows
- Adjudicated areas
- Critically overdrafted basins
- Groundwater-related transfers

Additional information about how each of these components were analyzed can be found in the process section of the 2019 SGMA Basin Prioritization Process and Results document.

The Bear Valley Groundwater Basin (Basin Number 8-009) was initially designated by the CDWR as a medium priority basin not subject to conditions of critical overdraft, requiring the formation

of the Bear Valley Basin Groundwater Sustainability Agency (BVBGSA) and preparation of a GSP for the GSA area. Given the fact that natural precipitation is the only source of recharge and water supply to the valley, the BVBGSA member agencies have already been proactive in implementing many of the groundwater monitoring and management elements required by SGMA in an effort to protect this critical resource. As such, the BVBGSA applied for and received a grant from CDWR to fund the preparation of the GSP. Following award of the grant, CDWR reclassified the Bear Valley Basin as a very low priority basin, but encouraged the BVBGSA to continue with the planned preparation of the GSP. Medium priority basins that are not in critical overdraft are scheduled to submit a GSP to CDWR by January 31, 2022.

1.4 Agency Information

The BVBGSA is a "local agency" comprised of the Big Bear City Community Services District (BBCCSD), the City of Big Bear Lake Department of Water and Power (BBLDWP), the Big Bear Regional Wastewater Agency (BBARWA) and the Big Bear Municipal Water District (BBMWD), each a member with water management responsibilities within the Bear Valley Groundwater Basin.

In 2017, the BBCCSD, BBMWD, BBARWA and BBLDWP elected to form a joint powers authority (JPA) to serve as the exclusive GSA for the entire Bear Valley Basin through a joint powers agreement. The Agency was created primarily to fulfill the role and legal obligations of a GSA for the Bear Valley Basin required by SGMA. The Agreement and Agency will continue to serve this role in full force until the governing bodies of the members unanimously elect to terminate the Agreement. Figure 2-1 shows the service area boundaries of each of the Agency parties and the GSA area.

1.4.1 Agencies Names and Mailing Addresses

The following contact information is provided for each member of the Bear Valley Basin Groundwater Sustainability Agency, pursuant to California Water Code §10723.8.

Big Bear City Community Services District
139 E. Big Bear Boulevard
P.O. Box 558
Big Bear, CA 92314
Attention: General Manager

City of Big Bear Lake Department of Water and Power
41972 Garstin Drive
P.O. Box 1929
Big Bear Lake, CA 92315

Attention: General Manager, Department of Water and Power

Big Bear Area Regional Wastewater Agency
121 Palomino Drive
Big Bear, CA 92314
Attention: General Manager

Big Bear Municipal Water District
40524 Lakeview Drive
P.O. Box 2863
Big Bear Lake, CA 92315
Attention: General Manager

1.4.2 Agency Organization and Management Structure

The JPA established the BVBGSA as a single GSA for the entire Bear Valley Basin to provide for the commitments reasonably anticipated to be necessary of ensuring that the Basin is sustainably managed in accordance with the timelines established by SGMA. The BVBGSA is governed by a Board of Directors which is composed of one (1) representative from BBCCSD, one (1) representative from BBARWA, one (1) elected representative from BBMWD and one (1) appointed commissioner from BBLDWP. Each BVBGSA Board member shall be entitled to one vote. A simple majority of the quorum (i.e. two-thirds) is required for any adoption of a motion, resolution, contract authorization or other action of the Board, except that:

1) A majority vote of less than a quorum may vote to adjourn;
2) Any of the following actions shall require a unanimous vote of the entire Board:
   a) Adoption, modification or alteration of the GSP or of the GSA boundaries;
   b) Adoption of assessments, charges or fees;
   c) Admission of additional Members to the BVBGSA;
   d) Setting the amounts of any contribution or fees to be made or paid to the BVBGSA by any Member; and
   e) Issuance of bonds or other indebtedness.

The officers of the BVBGSA includes a Chairperson, a Vice-Chairperson, a Treasurer and a Secretary. Names of the officers appointed to the Board of Directors are provided below:

Bob Ludecke, Chairman

Craig Hjorth, Treasurer

John Green, Vice Chairman

James Miller, Secretary

2. Bear Valley Basin Setting

The Bear Valley Groundwater Basin (No. 8-009) covers approximately 30 square miles within the San Bernardino Mountains in southern San Bernardino County, California (see Figure 2-1). Bear Valley extends from Big Bear Lake Dam on the west to the eastern portion of Baldwin Lake on the east. The basin is characterized by two major watersheds, each which encompasses the two primary surface water features in the area: Big Bear Lake and Baldwin Lake. The area of the Bear Valley Basin is defined by the latest version of California Department of Water Resources (CDWR) Bulletin 118 (CDWR, 2018) and is shown on Figure 2-1.

The Bear Valley Basin area includes the jurisdictional areas of multiple water districts and service entities, including Big Bear Lake Department of Water and Power (BBLDWP), Big Bear City Community Services District (BBCCSD), Big Bear Municipal Water District (BBMWD), and Big Bear Area Regional Wastewater Agency (BBARWA).

2.1 Hydrogeologic Conceptual Model

The hydrogeologic conceptual model is a description of the groundwater flow system of the Bear Valley Basin and how it interacts with surface water and land use of the area. The conceptual model includes a description of the geologic setting, geologic structure, and boundary conditions including the principal aquifers and aquitards. The hydrogeologic conceptual model of the Bear Valley Basin, as described herein, has been developed in accordance with the requirements of California Code of Regulations, Title 23, Division 2, Chapter 1.5, Subchapter 2, Article 5, Subarticle 2 (§354.14) and in consideration of CDWR's Best Management Practices (BMP) for the preparation of hydrogeologic conceptual models.

2.1.1. Sources of Data

Compilation, review, and analysis of multiple types of data were necessary to develop the hydrogeologic conceptual model and water budget of the Bear Valley Basin. The various types of data included geology, soils/lithology, hydrogeology, surface water hydrology, climate, land use, topography, remote sensing, and groundwater recharge and recovery. Data were obtained from multiple sources:

Geological Data including geologic maps and cross sections were obtained from the United States Geological Survey (USGS) and the California Geological Survey (CGS). Geophysical logs were obtained from reports provided by the City of Big Bear Lake Department of Water and Power (BBLDWP) and Big Bear City Community Services District (BBCCSD).

Lithological Data were obtained from drillers' logs and reports from the CDWR and detailed lithological logs from boreholes and wells drilled in the basin, as provided by BBLDWP and BBCCSD.

Hydrogeological Data including groundwater levels and pumping tests were obtained from the BBLDWP, BBCCSD, and Big Bear Area Regional Wastewater Agency (BBARWA).

Groundwater Quality Data from the BBLDWP, BBCCSD, California State Water Resources Control Board Department of Drinking Water Database, Environmental Data Resources, Inc. EDR Radius Map, and contaminants identified in the California State Water Resources Control Board Geotracker website (Geotracker, 2019).

Well Information including water well construction and well locations were obtained from CDWR driller's logs (private wells) and BBLDWP and BBCCSD (municipal wells).

Groundwater Production Data was obtained from BBLDWP and BBCCSD.

Hydrological (i.e. Surface Water) Data including Big Bear Lake surface water levels, natural inflows, and releases from the dam were obtained from BBMWD. Spring flow data was obtained from BBLDWP and BBCCSD. Information on the Baldwin Lake water balance was obtained from the USGS.

Climate/Precipitation Data was acquired from BBMWD, BBCCSD, the County of San Bernardino, CDWR's California Irrigation Management Information System (CIMIS), and the Western Regional Climate Center website.

Land Use Data was obtained from the CDWR, and the USGS Earth Resources Observation and Science Center. Political boundaries were obtained from the BBLDWP, BBCCSD, and BBMWD.

In addition to the various types of data, numerous historical reports on the geology, hydrogeology and groundwater management of the Bear Valley Basin were reviewed and analyzed. These reports included USGS publications, CDWR reports and bulletins, consultant reports, and academic publications. Publications relied on for the hydrogeological conceptual model and water budget are summarized in the References Section (Section 2.5).

2.1.2. Geologic Setting

Bear Valley Basin is situated at an elevation of approximately 6,740 feet above mean sea level (amsl) in the San Bernardino Mountains in the Transverse Ranges province of Southern California (Figure 2-1). It is located at the west end of a continuous east-west valley-like feature that extends from the west end of Big Bear Lake to the east end of Baldwin Lake. The surrounding mountain

slopes are relatively steep (as much as 70 degrees) and rugged. Prominent mountain peaks and ridges surrounding Big Bear Lake include Delamar Mountain to the north (8,398 feet amsl), Bertha Ridge and Gold Mountain to the northeast (8,201 and 8,235 feet amsl, respectively), Moon Ridge to the southeast (7,583 to 7,866 feet amsl), Sugarloaf Mountain to the southeast (9,952 feet amsl), and Snow Summit and Clark's Summit to the south (8,182 and 7,816 feet amsl; see Plate 1). Big Bear Lake receives surface runoff from several small canyons and valleys, the most prominent of which are Grout Creek to the northwest, Van Dusen Canyon to the northeast, Sawmill Canyon to the southeast, Sand Canyon to the southeast, and Knickerbocker Canyon and Metcalf Creek to the south.

The San Bernardino Mountains formed because of uplift along a complex system of faults, including the San Andreas Fault System, which separates the San Bernardino Mountains from the neighboring San Gabriel Mountains to the west. Most of the tectonic activity that created the mountains occurred during Late Pliocene and Pleistocene times (2.6 million years ago to 12,000 years ago). However, uplift continues to occur at a rate of approximately 30 inches every 100 years. The June 28, 1992 Big Bear earthquake is evidence of the continued tectonic activity in the area.

In the Bear Valley Basin area, the San Bernardino Mountains consist primarily of Mesozoic granitic intrusive rocks, with lesser outcrops of Precambrian and Late Paleozoic metamorphic rock (see Figure 2-2). Geologic formations observed at the land surface and in the subsurface beneath the Bear Valley Basin can be grouped into three primary geologic formations, described below in order of increasing age:

Quaternary Alluvial Deposits – This unit consists of primarily Quaternary age (approximately 2.5 million years ago to present) clay and sandy clay with interbedded sand and gravel layers near Big Bear Lake and coarsens to predominately sand with some gravel and interbedded layers of silt and clay towards Baldwin Lake. Beneath Baldwin Lake, alluvial deposits consist of lacustrine (historical lake) deposits mostly consisting of clay, silt and interbedded sand. The coarse-grained layers make up the water-bearing aquifer in which wells pump from.

Recent alluvium is comprised of permeable sand and gravel with lesser interbedded layers of silt and clay. Most recent alluvium is located above the water table but where it is present, this permeable layer allows for infiltration of rainfall and runoff into the subsurface (Geoscience, 2004; Flint and Martin, 2012).

Tertiary Sedimentary Deposits – These sediments overlie the basement rocks throughout most of the Bear Valley Basin and are Tertiary age (approximately 65 million years ago to 2.6 million years ago). This unit consists primarily of consolidated to semi-consolidated

alluvial fan deposits of gravel, sand and clay. Some municipal wells have been constructed in these Tertiary deposits, but they are less permeable than overlying Quaternary sediments and do not yield significant water. Tertiary sedimentary deposits are exposed at the land surface southeast of Big Bear Lake in the Sugarloaf area, along the base of the hills on the north side of Big Bear Lake, and in the Lake Williams area. This unit is greater than 1,000 ft thick in the Sugarloaf area (Geoscience, 2005).

Pre-Tertiary Bedrock – Basement rocks underlying the Tertiary and Quaternary sediments consist of Cretaceous (65 to 145 million years ago) granitic rocks, Paleozoic (252 to 541 million years ago) sedimentary rocks consisting of limestone, and Proterozoic (older than 541 million years) metamorphosed sedimentary rocks consisting of quartzite and gneiss (Miller, 2004). The permeability of the geologic formations making up the basement rocks is generally very low and they are not considered major water-bearing units in the Bear Valley Basin. However, localized fractures in this bedrock allow for some groundwater production via springs and bedrock wells. The BBLDWP Cherokee Well in Fawnskin produces groundwater from fractures in the granitic rock in this area. BBLDWP's Lassen Well is constructed within fractures in the limestone south of Big Bear Lake.

The most significant fault near the Bear Valley Basin is the San Andreas Fault zone. The San Andreas Fault is a strike-slip fault that bounds the south side of the San Bernardino Mountains. A significant zone of frontal reverse faults exist on the north side of the mountains. These faults account for the uplift in the San Bernardino Mountains (Miller, 1987).

2.1.3. Lateral Basin Boundaries

The lateral boundaries of the Bear Valley Basin are defined by the surface contact between crystalline rocks of the San Bernardino Mountains and surficial alluvial sediments within the valley floors (see Figure 2-2). The westernmost extent of the basin is defined by the Big Bear Lake dam. The total area of the Bear Valley Basin is approximately 30 square miles (19,155 acres).

2.1.4. Bottom of Basin

The physical bottom of the Bear Valley Basin is defined by the interface between the Tertiary sedimentary deposits and the relatively impermeable crystalline basement complex underlying them. Variations in the thickness of alluvial sediments throughout the basin, based on both borehole intercepts and a gravity survey (Flint and Martin, 2012), is shown on Figure 2-3 and Plates 1 and 2). As shown, the alluvial/tertiary sedimentary thickness in some areas of the basin

exceeds 1,500 feet. However, the most permeable sediments, and the most productive aquifers for groundwater supply, are generally in the upper 500 feet of alluvial sediments.

2.1.5. Surface Water Features

The Bear Valley Basin is encompassed by two major watersheds: the Big Bear Lake Watershed at the west end of the basin and the Baldwin Lake Watershed at the east end of the basin.

The Big Bear Lake Watershed covers an area of approximately 38.5 square miles and delineates the area where surface water drains into Big Bear Lake (see Figure 2-4). The Big Bear Lake Watershed has been divided into seven hydrologic subareas: Gray's Landing, Grout Creek, North Shore, Division, Rathbone, Village, and Mill Creek (LeRoy Crandall & Associates, 1987a). The subareas are delineated based on surface water drainage divides.

The Baldwin Lake Watershed covers an area of approximately 34.3 square miles and delineates the area where surface water drains into Baldwin Lake. This watershed is divided into four hydrologic subareas: Erwin, West Baldwin, East Baldwin, and Van Dusen (LeRoy Crandall & Associates, 1987b).

2.1.5.1 Big Bear Lake

Big Bear Lake is a manmade reservoir that is fed by runoff from creeks that drain the mountains and valley floor within the Big Bear Lake watershed (see Figure 2-4). The maximum surface area of the lake is 2,971 acres and, when full, the lake storage capacity is approximately 73,320 acre-ft. At its deepest point at the dam, the lake is approximately 70 feet deep. Lake surface water elevations typically range from 6,743 feet above mean sea level (ft amsl) when full to 6,725 ft amsl during dry periods.

The dam that contains the lake was originally built in 1884 and then rebuilt in 1912 to create a reservoir to meet irrigation needs of downstream growers. The BBMWD manages lake levels in the context of water demands from downstream water rights holders and recreational uses for the local area. Downstream water demands are met through releases of lake water at the dam or from in-lieu water purchase agreements. Local recreational uses of the water include fishing and boating as well as water supply for snowmaking at the local ski resorts.

2.1.5.2 Baldwin Lake

Baldwin Lake is classified as a mountain playa. The lake is usually dry but periodically contains standing water during years of high rainfall. The surface area of this lake is approximately 1,500 acres (Johnson, 1994). During years of high rainfall, the surface water elevation of the lake can reach 6,707 feet (Johnson, 1994) with a corresponding lake depth of approximately 12 feet at

its deepest point. Surface water runoff into Baldwin Lake occurs via Van Dusen Canyon to the northwest and Shay Creek to the south (see Figure 2-4).

Surface water sources to Baldwin Lake are primarily in the form of ephemeral streams with relatively low flow volumes. The only stream where surface water flow has been periodically measured is Shay Creek at its outlet from Shay Pond (see Figure 2-4). During most years, surface water runoff does not reach Baldwin Lake but percolates into the groundwater system. However, during prolonged precipitation, surface water does collect in Baldwin Lake.

All surface water that enters Baldwin Lake is lost to evaporation. The high clay content of the playa sediments prevents vertical migration and the topographical configuration of the lake prevents surface runoff.

2.1.5.3 Lake Erwin

Lake Erwin is a small mountain playa located approximately one mile southeast of Baldwin Lake within the Erwin Hydrologic Subunit (see Figure 2-4). This lake contains water only during periods of high rainfall. The lake is fed from runoff in ephemeral streams that drain the hills to the north and south. The lake is also fed from the east via an unnamed stream that drains out of Gocke Valley to the south. There are no records available regarding surface water inflow to this lake.

2.1.5.4 Springs

Numerous springs feed ephemeral streams in the Big Bear Lake and Baldwin Lake watershed areas. Many of the springs have measurable flow at least part of the year and some are tapped by the BBLDWP and BBCCSD as sources of municipal water supply.

Big Bear Lake Watershed

Prominent springs utilized for water supply in the Big Bear Lake Watershed include Cedar Springs (Grout Creek subunit) and Dogwood Springs (Rathbone subunit) (see Figure 2-4). Water from these springs is captured by the BBLDWP for municipal water supply in the respective hydrologic subunits within which they are located. Annual production from the Cedar Springs (Cedar Dell Slant Wells) between 1990 and 2019 has been 32.5 acre-ft/yr. Annual production from the Dogwood Springs (Dogwood Slant Wells) between 1990 and 2019 has been 123 acre-ft/yr.

Baldwin Lake Watershed

Prominent springs utilized for water supply in the Baldwin Lake Watershed include the Greenspot and Fish Hatchery Springs (Erwin Subunit), and Van Dusen Slant Wells (Van Dusen Subunit).

Greenspot and Fish Hatchery Springs typically flow year-round and are used by BBCCSD for municipal water supply. The Van Dusen Slant Wells enhance a natural spring in Van Dusen Canyon for BBCCSD water supply. Water supply from the combined Green Spot Springs and Van Dusen Slant Wells averages approximately 190 acre-ft/yr.

Shay Pond is a natural surface water body at the southern base of an unnamed ridge that separates it from Baldwin Lake in the northern part of the Erwin Subunit. The nature of this pond is unknown, but it may be fed, in part, from spring flow, surface runoff, and periodically, groundwater intersecting the land surface. Although the pond may have historically been fed from surface water runoff in the ephemeral stream Shay Creek, urban development has altered the course of this stream and it no longer outlets into the pond. Surface water exits Shay Pond via Shay Creek, which flows northwards into Baldwin Lake.

2.2 Areas of Groundwater Recharge and Discharge

2.2.1 Recharge

Groundwater recharge in the Bear Valley Basin occurs from deep percolation of precipitation that falls on the younger alluvium and fractures in the bedrock and infiltration of surface runoff in ephemeral streams and soft bottom washes. The majority of natural recharge occurs in areas where Young Alluvial Fan Deposits are mapped at the land surface (see Figure 2-2).

Numerous studies have been conducted to identify areas favorable for artificial recharge of the aquifer system in the Bear Valley (Geoscience, 1990; Geoscience, 2004a; TH&Co, 2017). Areas that are most promising occur in or near ephemeral stream channels that are characterized geologically by recent alluvium or stream channel sediments (sand and gravel) and where the groundwater table is greater than 50 ft below ground surface (bgs). Areas of favorable recharge identified from previous studies are shown on Figure 2-5. These areas include the Sand Canyon area on the south side of Big Bear Lake in the Rathbone Subunit, the area north of Green Spot Spring in the Erwin Subunit south of Baldwin Lake, and Van Dusen Canyon north of Baldwin Lake. Favorability for recharge has been supported through analysis of both borehole testing and pilot-scale recharge tests (Geoscience, 2004a).

2.2.2 Discharge

The Bear Valley Basin is a closed basin with no natural outlets for groundwater outflow. Natural groundwater discharge within the basin occurs from numerous springs located throughout the basin (see Figure 2-4; Section 2.1.5.4). This spring flow is either captured by local agencies for municipal water supply or discharges into ephemeral washes and infiltrates into the subsurface.

During periods of prolonged above-normal precipitation, it is possible that some uncaptured spring flow from Green Spot Spring enters Baldwin Lake where it eventually evaporates.

Some discharge of groundwater occurs through evapotranspiration in areas where groundwater rises near the land surface during periods of high precipitation. These areas include the immediate Shay Pond area in the Erwin Subunit, parts of west Baldwin Lake, and the outlet of Rathbun Creek to Big Bear Lake.

The primary source of groundwater discharge within the Bear Valley Basin is groundwater pumping (see Section 2.3.2.2). Groundwater pumping is conducted from both municipal and private wells. There are 72 municipal groundwater production wells in the Bear Valley Basin (55 operated by BBLDWP and 15 operated by BBCCSD) (see Figure 2-6). There are numerous private wells located throughout the Bear Valley Basin, as many as 445 private wells have been documented from CDWR driller's logs as of 2019. Some of these wells have been verified in the field. However, the exact number of private wells is not known as many have been destroyed, others are inactive, and some may have been drilled but not properly recorded.

2.3 Principal Aquifer and Aquitards

2.3.1 Aquifer Formations

In general, groundwater is produced from three hydrogeological units in the subsurface beneath the Bear Valley Basin (see Plates 1 and 2):

1. Unconsolidated or semi-consolidated alluvial sediments
2. Fractures in Granitic Bedrock
3. Fractures and cavities in Carbonate Bedrock

Unconsolidated to Semi-Consolidated Alluvial Aquifer

Previous reports for the eastern portion of the Bear Valley Basin have described three individual aquifers within the unconsolidated to semi-consolidated alluvial sediments: an upper, middle, and lower aquifer (Geoscience, 1999). For this report, the prior designations have been extended to the remaining parts of the Bear Valley Basin, based on lithologic characteristics, permeability, and groundwater quality.

The upper aquifer consists of younger alluvium and is characterized by more permeable sand and gravel that occurs primarily within the major drainage channels (e.g. Shay Creek) and in the north central portion of the basin between Big Bear and Baldwin lakes. In general, the upper aquifer is

approximately 50 ft thick. This aquifer is the most permeable of the alluvial aquifer units but is locally unsaturated during dry climatic cycles. This aquifer is considered unconfined.

The middle aquifer consists of older alluvium and older fan deposits and is characterized by locally thick layers of silt and clay with relatively thin layers of sand and gravel. This aquifer extends throughout the basin and is approximately 150 feet thick to greater than 800 feet thick. Most of the municipal wells within the Bear Valley Basin are perforated within the middle aquifer because the sand and gravel layers within this unit are moderately permeable and yield economic quantities of water and the groundwater quality is very good. Groundwater production rates in wells perforated in this aquifer range from approximately 50 gpm to 1,000 gpm. This aquifer is confined.

The lower aquifer is characterized by gravel, coarse sand, pebbles and interbedded sandy clay in north central portion of the basin but is predominantly clay in the southern portion of the basin. While some municipal wells have been completed with perforations extending into the lower aquifer, it is characterized by relatively low permeability and high concentrations of naturally occurring fluoride and arsenic in groundwater at depth, which have prevented utilizing this aquifer for water supply.

Fractured Granitic Bedrock Aquifer

A small number of vertical wells have been constructed within the granitic bedrock on the north side of Bear Valley Basin. The BBLDWP Cherokee Well, in Fawnskin, produces groundwater from fractures in the granitic bedrock. This well is capable of producing discharge rates as high as approximately 60 gallons per minute (gpm), which is lower than most of the wells perforated in the alluvial aquifer system. Some private wells on the north side of Big Bear Lake are also known to be completed in the granitic bedrock. Individual well production rates from these wells are expected to be on the order of those observed in the Cherokee Well, or lower.

Fractured Carbonate Bedrock Aquifer

The BBLDWP operates one well that produces groundwater from the carbonate bedrock (Lassen Well No. 4). This well is located south of Big Bear Lake within the Rathbone Subunit.

2.3.2 Aquifer Physical Properties

The ability of aquifer sediments to transmit and store water is described in terms of the aquifer parameters transmissivity, hydraulic conductivity, and storativity. The most reliable estimates of these parameters are obtained from long-term (e.g. 24-hr or more constant rate) controlled pumping tests in wells. In the absence of this type of test, estimates can be obtained through short-term pumping tests and/or assignment of literature values based on the soil types observed in

driller's logs. Long-term pumping test data was obtained from BBLDWP and BBCCSD. Short-term pumping test data was obtained from driller's logs.

Transmissivity is a measure of the ability of groundwater to flow within an aquifer and is defined as the rate of groundwater flow through a unit width of aquifer under a unit hydraulic gradient (Fetter, 1994). Transmissivity was estimated from short-term pumping test data based on Theis et al., 1963 and the following relationship:

$$T = \frac{S_c \, x \, 2{,}000}{E}$$

Where:

T	=	Transmissivity (gpd/ft);
S_c	=	Specific Capacity (gpm/ft);
E	=	Well Efficiency (assumed to be 0.7)

Transmissivity values at individual wells were converted into hydraulic conductivity (i.e. aquifer permeability) by dividing by the aquifer thickness (in this case the perforation interval of the well). Horizontal hydraulic conductivity values for the alluvial aquifer are summarized in Table 2-1 and shown on Figure 2-7 and range from less than 1 ft/day to approximately 130 ft/day, the higher values indicating more permeable sediments.

Storage properties of the upper aquifer are expressed in terms of specific yield since most of this aquifer is conceptualized as unconfined. Specific yield is the ratio of the volume of water sediment will yield by gravity drainage to the volume of the sediment. The only specific yield value available for the upper aquifer is in the Erwin Subunit, where pumping tests and pilot recharge testing resulted in a value of 0.03 (see Figure 2-8).

The middle aquifer is confined and, as such, storage properties for this aquifer are expressed in terms of storativity. Storativity is a measure of the volume of water an aquifer can release from, or take into, storage per unit of aquifer surface area per unit change in hydraulic head. Storativity is derived from long-term pumping tests where pumping interference is measured in a monitoring well located a known distance from the pumping well. Values for storativity in the middle aquifer range from 0.00003 to 0.0006 (see Table 2-1; Figure 2-8). These values indicate confined aquifer conditions.

No storage property data are available for the lower aquifer or bedrock aquifers.

2.3.3 Geologic Structures that Affect Groundwater Flow

Numerous small unnamed faults have been mapped throughout the Bear Valley Basin (Sadler, 1982; Ron Barto & Associates, 1988). The only fault that has been observed to affect groundwater flow is an inferred fault that extends in a northeast/southwest trend at the west end of Lake Erwin (see Figure 2-2). The fault was inferred based on groundwater level differences on each side of the fault. The Bear Valley Basin is seismically active, as demonstrated from the 1992 Big Bear earthquake. Coincident with that earthquake, groundwater levels in some monitoring wells in the Erwin subunit changed significantly (Geoscience, 2001) and some wells along Baldwin Lake began flowing artesian (Heule, 1992). Thus, seismic activity in the area does impact groundwater flow although the correlation with specific faults is not known.

2.3.4 Aquifer Water Quality

Groundwater quality in the Bear Valley Basin varies across the basin and with depth in the aquifer system. Overall, the native groundwater quality of the upper and middle aquifers from which local agencies produce water is generally very good, with historical total dissolved solids (TDS) measurements generally in the range of 200 to 300 milligrams per liter (mg/L) with no detections above 500 mg/L (see Figure 2-9). Groundwater quality issues in the subbasin include both regional non-point groundwater quality issues and point-source contaminant issues.

Fluoride is a naturally occurring non-point constituent of concern in the Baldwin Lake and Lake William areas (see Figure 2-10). Concentrations of this constituent generally increase with increasing depth in the aquifer system where it is present. Depth-specific water quality sampling in wells near Baldwin Lake (e.g. BBCCSD's Wells 8, 9 and 10) have shown that fluoride concentrations below a depth of approximately 350 feet are generally higher than the maximum contaminant level (MCL) for this constituent of 2 mg/L (Geoscience 2003a, Geoscience, 2003b, and Geoscience, 2003c). This depth generally defines the boundary between the middle aquifer system and lower aquifer system in the Baldwin Lake area. Construction of most of the newer wells in this area is limited to the middle aquifer due to high fluoride in the deep aquifer. One exception is BBCCSD's Well 3B, located at the southwestern edge of Baldwin Lake. Depth-specific isolated aquifer zone testing showed that fluoride concentrations ranged from 6.3 mg/L at a depth of 300 to 320 ft bgs to 9.0 mg/L at a depth of 480 to 500 ft bgs (Geoscience, 2000).

Other naturally occurring groundwater quality constituents of concern have included arsenic, manganese, and uranium. Arsenic has been detected in samples from wells in the Grout Creek subunit (Cherokee Well), Rathbone Subunit (Owen Well) and Mill Creek Subunit (Canvasback test borehole) (see Figure 2-11). The arsenic concentration in the Canvasback test borehole was 88 μg/L and was detected in a depth-specific sample collected from 499 ft bgs (Geoscience,

2003d). Arsenic has not been detected in a shallower well completed near the test hole to a depth of 315 ft bgs, indicating the arsenic concentrations are unique to a deeper aquifer system at the site (Geoscience, 2004b). All other arsenic concentrations detected in the Big Bear Valley have been below the MCL. Uranium has been detected in the Canvasback Well at concentrations above the MCL. Manganese has been detected above its secondary MCL in wells in the Village Subunit and Division Subunit.

For point-source contaminants, there are nine active cleanup sites in the Bear Valley Basin identified on the California Geotracker website (see Figure 2-12; Table 2-2). Seven of the point source contamination sites are associated with leaking underground storage tanks (LUSTs) for which the primary contaminants are gasoline, methyl tert-butyl ether (MTBE), tertiary butyl alcohol (TBA) and/or other oxygenates. There is one Department of Toxic Substance Control (DTSC) site and one land disposal site listed within the basin (see Figure 2-12). Contaminants associated with these sites are not reported on the Geotracker website.

2.3.5 Aquifer Primary Uses

The predominant beneficial use of groundwater in the Bear Valley Basin is municipal water supply. The other beneficial use is private domestic water supply.

2.4 Uncertainty in the Hydrogeologic Conceptual Model

The primary sources of uncertainty in the hydrogeologic conceptual model include:

- Precipitation distribution across the Bear Valley Basin
- The surface water balance of Baldwin Lake
- Areal recharge from precipitation
- Tributary channel infiltration
- The nature of the aquifer system beneath Big Bear Lake.
- Aquifer characteristics of hydraulic conductivity, transmissivity and storativity.

2.5 Groundwater Conditions

2.5.1 Groundwater Occurrence and Flow

Most of the groundwater within the Bear Valley Basin occurs in the permeable sediments that make up the alluvium of the basin. Groundwater in the upper aquifer is unconfined. Groundwater in the older alluvial fan sediments of the middle and lower aquifers are confined. Groundwater also occurs in the secondary porosity features (i.e. fractures and cavities) within the granitic and limestone bedrock.

Groundwater in the Bear Valley Basin flows by gravity drainage from areas of recharge along the flanks of the surrounding mountains towards Big Bear Lake and Baldwin Lake (see Figures 2-13 through 2-16). In the western portion of the basin south of Big Bear Lake, groundwater flows to the northwest towards the lake and towards a groundwater pumping depression in the Village Subunit (see Figures 2-13 and 2-15). In the eastern portion of the Basin south of Baldwin Lake, groundwater flows to the north towards the center of the basin and Baldwin Lake. A slight groundwater pumping depression is present in the northwestern part of the Erwin Subunit (see Figures 2-14 and 2-16). There is also a groundwater flow divide in the north central part of the basin between Big Bear Lake and Baldwin Lake. The divide occurs in the vicinity of the outlet of Van Dusen Canyon where groundwater west of the canyon flows to the west and groundwater east of the canyon flows to the east.

Changes in groundwater levels over time vary from hydrologic subunit to hydrologic subunit as a function of the geology of the area, groundwater production, and precipitation patterns. Monitoring wells with historical groundwater level data are in the Grout Creek, North Shore, Mill Creek, Village, Rathbone, Division, West Baldwin and Erwin hydrologic subunits.

Grout Creek Subunit

Historical groundwater levels in the Grout Creek Subunit are documented for the Seminole Well with a period of record from 1996 to 2019 (see Figure 2-17). This well is relatively shallow (less than 100 feet deep) and perforated in alluvium that is known to be hydrologically connected with Big Bear Lake. Groundwater levels in this well have ranged from approximately 6,738 and 6,755 ft amsl (7 to 24 feet below land surface). Groundwater levels throughout the period of record have been relatively stable and, while dropping during dry climatic cycles, rise to historical high levels during wet precipitation cycles.

Groundwater levels in the bedrock aquifer, as indicated by measurements in the Cherokee Well, are at a similar elevation and range as the Seminole Well, ranging from approximately 6,739 to 6,758 ft amsl. The groundwater level trend has been relatively stable since the start of data collection in 2013.

North Shore Subunit

Groundwater level data are available for two wells that supply water for a recreational vehicle park on the north side of Big Bear Lake (RV Park Well Nos. 1 and 2) (see Figure 2-18). The period of record for these wells is from 1996 to 2019. Static groundwater levels in RV Park Well No. 1 have ranged from approximately 6,750 to 6,785 ft amsl. Since approximately 2011, groundwater levels in this well have shown a slight downward trend, dropping a total of approximately 20 feet.

Static groundwater levels in RV Park Well No. 2 have ranged from approximately 6,780 to 6,820 ft amsl. Groundwater levels in this well have remained relatively stable.

Groundwater levels in the Stanfield Monitoring Well, located on the east side of the North Shore Subunit, have ranged from approximately 6,740 ft amsl to 6,780 ft amsl (see Figure 2-18). Groundwater levels in this monitoring well track very closely with surface water levels in Big Bear Lake indicating that the shallow groundwater level at this location is likely in hydrologic communication with surface water in the lake.

Mill Creek Subunit

Historical groundwater levels are available for three monitoring wells in the Mill Creek Subunit: Metcalf, Canvasback Well and Mallard Well (Figure 2-19). The Canvasback and Mallard wells are nested, with isolated perforations in the Middle and Lower aquifers. Static groundwater levels in most of the wells are around 6,760 ft amsl. The groundwater level in the Lower Aquifer Canvasback well completion is 6,780 ft amsl, approximately 20 feet higher than the Middle Aquifer groundwater level and indicating confined aquifer conditions. Groundwater levels dropped approximately 100 feet at the Canvasback Middle Aquifer monitoring well in 2007 when BBLDWP began pumping the Canvasback production well, located approximately 50 feet from the monitoring well. Due to water quality issues, pumping from the Canvasback production well was discontinued shortly after and groundwater levels returned to their pre-pumping elevation. Groundwater levels in the Mill Creek Subunit are stable.

Village Subunit

The BBLDWP's Pennsylvania and Knickerbocker wells are used as monitoring wells in the Village Subunit (see Figure 2-20). Static groundwater levels in the Pennsylvania Well were as high as 6,730 ft amsl in 1996 before declining steadily to an elevation of approximately 6,690 ft amsl in 2004. After that time, BBLDWP reduced groundwater production in the Village Subunit to allow groundwater levels to recover. Since 2004, groundwater levels have been recovering or steady in both the Pennsylvania and Knickerbocker wells.

Rathbone Subunit

Three wells used for measuring groundwater levels in the Rathbone Subunit are the Sand Canyon Well (irrigation), Rathbone Fire Station Monitoring Well, and Elm Monitoring Well (see Figure 2-21). Groundwater levels in the Sand Canyon well have dropped over time from approximately 7,000 ft amsl in 1992 to approximately 6,920 ft amsl in 2004 and then again in 2019. During above-average precipitation years, the groundwater level rises as much as 60 feet but have not recovered to the historical high level observed in 1992. Groundwater levels in the Middle Aquifer

of the Rathbone Fire Station Well, located downgradient of the Sand Canyon Well, have shown a declining trend, dropping approximately 10 feet from 6,870 ft amsl in 2006 to 6,860 ft amsl in 2019. Groundwater levels measured in 2019 in the Elm Monitoring Well, downgradient from Rathbone Monitoring Well, are approximately five feet lower than groundwater levels measured at the historical high level in 1998.

Division Subunit

Monitoring wells used to measure groundwater levels in the Division Subunit are shown on Figure 2-22. These wells include the McAlister Nested Monitoring Well (Middle and Lower Aquifers), the Riffenburgh Monitoring Well, Division Well No. 4 (inactive production well used as a monitoring well), and Hillendale Monitoring Well. Except for the deep completion of the McAlister Nested Monitoring Well, all of these wells are perforated in the Middle Aquifer.

Groundwater levels in both McAlister Nested Monitoring Wells are similar when the McAlister production well (located approximately 100 feet away) is not pumping. The McAlister production well is perforated in the Middle Aquifer so when it is pumping, the interference in the shallow (Middle Aquifer) completed monitoring well is greater than the deep completion. Aside from an initial groundwater level decline when the McAlister production well was activated in 2006, groundwater levels in the monitoring wells are relatively stable.

The Riffenburgh Monitoring Well, Division Well No. 4 and Hillendale Monitoring Well are all located in the center of Big Bear Valley in the north-central part of the Bear Valley Basin. Prior to 2011, groundwater levels in these wells would periodically drop during dry climatic cycles but would rebound to historical high conditions during above average periods of precipitation. Between 2011 and 2019, a period characterized by historically dry climatic conditions, groundwater levels have remained approximately 20 to 40 feet below the previous historical high.

West Baldwin Subunit

Monitoring wells used to measure groundwater levels in the West Baldwin Subunit are shown on Figure 2-23. These wells include the Greenway, Maltby, and Van Dusen No. 1 monitoring wells. Greenway and Maltby monitoring wells are in the center of Big Bear Valley in the north-central part of the Bear Valley Basin. Van Dusen No. 1 monitoring well is in Van Dusen canyon. Groundwater levels in the Greenway and Maltby monitoring wells follow a similar pattern as the Division monitoring wells to the west, whereby they periodically drop during dry climatic cycles but rebound to historical high conditions during above average periods of precipitation. Since 2011, groundwater levels have remained approximately 20 to 40 feet below the previous historical high due to historically dry climatic conditions.

Erwin Subunit

Monitoring wells used to measure groundwater levels in the Erwin Subunit are shown on Figure 2-24. These wells include the Magnolia, Erwin, Vaqueros, and Monte Vista monitoring wells. Groundwater levels at the Erwin and Vaqueros monitoring wells are sensitive to precipitation events, showing short-duration peaks during these times. Aside from the groundwater level peaks, groundwater levels in Erwin Monitoring Well have returned to historical high conditions, except for the historically dry period from 2011 to 2019, during which they have been approximately 15 feet below historical high conditions. Groundwater levels in the Vaqueros Monitoring Well have been relatively stable. Groundwater levels in the Magnolia Monitoring Well were on a slight downward trend between 2006 and 2011 but began dropping at a faster rate when the Magnolia production well, located approximately 50 feet from the monitoring well, began pumping in 2012.

Groundwater levels in the Monte Vista Monitoring Well, located in the Lake Williams Tributary Subarea of the Erwin Subunit, are responsive to precipitation rates and local pumping. Groundwater levels rose approximately 30 feet in 2005 in response to a significant above-average precipitation year. From 2005 to 2015, groundwater levels declined but then stabilized after 2015 when groundwater production from the nearby Monte Vista production well was discontinued.

2.5.2 Groundwater Storage

Changes in groundwater storage within the Bear Valley Basin have been estimated through analysis of the water budget for the basin. Annual change in groundwater storage in the basin between 1990/91 and 2018/19 is shown in Table 2-4 and is graphically presented on Figure 2-25. Comparison of the groundwater inflow elements of the water budget with the outflow elements shows a cumulative change in groundwater storage over the 29-year period between 1990/91 and 2018/19 of approximately 60,100 acre-ft. The average annual change in storage resulting from the groundwater budget is approximately 2,100 acre-ft/yr over this time period. It is noted that the beginning of the period (1990/91) was the end of a dry climatic cycle and groundwater levels were relatively low. From 1990/91 through 1998/99 was relatively wet resulting in an increase in water in aquifer storage over the time period.

2.5.3 Seawater Intrusion

Seawater intrusion cannot occur in the Bear Valley Basin due to its location with respect to the Pacific Ocean. The Bear Valley Basin is an isolated mountain groundwater basin located approximately 70 miles inland of the Pacific Ocean (see Figure 2-1). This mountain aquifer system is separated hydraulically from the coastal aquifers that are susceptible to seawater intrusion.

2.5.4 Groundwater Quality Issues

The primary groundwater quality issues that could affect the beneficial uses of groundwater in the Bear Valley Basin are naturally occurring fluoride, arsenic, uranium as well as petroleum releases from leaking underground storage tank (LUST) sites. Fluoride has been detected at concentrations above the MCL in lower aquifer groundwater in the Baldwin Lake area, which limits the use of deeper groundwater for municipal supply. Arsenic and uranium detected in groundwater in the Mill Creek subunit prohibits groundwater production in this area for municipal supply without wellhead treatment. For point-source contaminants, there are nine active cleanup sites in the Bear Valley Basin identified on the California Geotracker website (see Figure 2-12; Table 2-2). Seven of the point source contamination sites are associated with LUSTs for which the primary contaminants are gasoline, MTBE, TBA and/or other oxygenates. There is one DTSC site and one land disposal site within the basin (see Figure 2-12). Contaminants associated with these sites are not available.

While manganese has been detected in groundwater in the Village and Division subunits, treatment systems have been implemented to remove the manganese. Fluoride concentrations in groundwater produced from the Baldwin Lake area are mitigated through blending with spring water sources and groundwater from wells with low fluoride concentrations.

2.5.5 Land Subsidence

Analyses of land subsidence in the Bear Valley Basin using satellite data shows very low amounts of land deformation. The USGS analyzed Interferometic Synthetic Aperture Radar (InSAR) data for the time periods 1995 to 1997 and 2004 to 2005. Land deformation was observed in the Village and Rathbone subunit areas, the Sugarloaf area of the Erwin Subunit, and in the area between Big Bear and Baldwin lakes (Flint and Martin, 2012). As much as 1.2 inches of land subsidence was observed in the area between Big Bear and Baldwin lakes between 1995 and 1997. In contrast, as much as 1.2 inches of uplift was observed in the same area between 2004 and 2005. As the time periods include extremes in groundwater level fluctuations in the basin, it is likely that the subsidence and later uplift is elastic and recoverable. Analysis of InSAR data for the period from 2015 through 2018, a period of declining groundwater levels in the Bear Valley Basin, did not result in land subsidence greater than 3 inches in any parts of the basin (the limit of resolution of the data).

2.5.6 Interconnected Surface Water Systems

Groundwater is periodically in hydrologic connection with surface water in Big Bear Lake in the northwest part of the basin (Fawnskin area) and in the eastern part of the lake in the vicinity of BBLDWP's Division wells. In the Fawnskin area, BBLDWP's Seminole Well is constructed with

shallow perforations and is within 500 feet of the high-water line of Big Bear Lake. This well is generally considered to be pumping groundwater that is in direct hydrologic connection with the lake. As such, groundwater produced from this well is treated prior to distribution for municipal supply. Certain older Division Wells, located on the east end of Big Bear Lake, have perforations that begin at 50 ft bgs. Groundwater level trends measured in these wells match surface water elevation changes in Big Bear Lake when groundwater levels are high. During low groundwater level conditions, the surface water elevation changes do not match groundwater level trends suggesting that the hydrologic connection only occurs during high groundwater conditions (TH&Co, 2020). Wells with deeper perforations do not show the connection.

The natural springs at the margins of the Bear Valley Basin appear to be fed from the bedrock aquifer system. All springs utilized for municipal supply by the BBLDWP and BBCCSD are located within areas of bedrock. Flow from the springs is associated with available precipitation and flow rates are highly sensitive to climatic cycles. There is no upgradient groundwater production that would artificially impact the flow of the springs.

Shay Pond is a natural surface water body in the northern part of the Erwin Subunit, as described in Section 3.1.5. Most of the time, the only natural source of water supporting the pond is surface water flow from Shay Creek and surrounding areas. During high groundwater conditions after prolonged periods of above average precipitation, the groundwater may rise above the land surface and provide a source of water to the pond (TH&Co, 2017a). The BBCCSD provides supplemental water to the pond via a well located near the pond.

2.5.7 Groundwater Dependent Ecosystems

Groundwater dependent ecosystems require shallow groundwater or groundwater that discharges at the land surface. Groundwater levels in some areas of the Bear Valley Basin are periodically shallow enough to support groundwater dependent ecosystems. The areas most likely to support groundwater dependent vegetation are at the margins of Big Bear Lake in the Rathbone and Mill Creek Subunits, across much of the Baldwin Lake lakebed, and in the Shay Creek drainage downstream of Erwin Lake (see Figure 2-26).

2.6 Water Budget

2.6.1 Surface Water Budget

The surface water budget for the Bear Valley Basin was developed for the 30-year period from 1990/91 to 2018/19 (see Table 2-3). Inflow terms for the surface water budget include precipitation, natural lake inflows to Big Bear Lake and Baldwin Lake, discharge to the land surface from wells, and groundwater discharge to surface water (i.e. springs). Outflow terms

include areal recharge from precipitation, lake evaporation, tributary channel infiltration, return flow, municipal distribution pipeline losses, evapotranspiration (ET), Big Bear Lake withdrawals, measured releases at the Bear Valley Dam, and discharges to Lucerne Valley from BBARWA.

Ideally, the total surface water inflow to the basin would equal the total surface water outflow, indicating a complete accounting of water at the surface. In reality, there is uncertainty in many of the surface water budget terms for the Bear Valley Basin that does not allow for a perfect surface water accounting. These include estimates for precipitation recharge, tributary channel inflow, and return flow. For the Bear Valley Basin surface water budget, the percent difference between the average annual surface water inflow (89,660 acre-ft; Table 2-3) and average annual outflow (89,686 acre-ft) is less than 0.0001 percent. This represents a very good match between surface water inflows and outflows and indicates that the water budget is a good representation of actual conditions. As additional data become available, it is anticipated that the surface water budget will become more accurate with time.

It is noted that many of the surface water outflow terms are also groundwater inflow (i.e. groundwater recharge) terms.

Details of the individual surface water budget terms are provided in the following sections.

2.6.1.1 Surface Water Inflow

Precipitation

The annual volume of water entering the Bear Valley Basin as precipitation was estimated based on the long-term average annual isohyet map shown on Figure 2-27 and the annual precipitation data reported for the BBCCSD precipitation station and the Big Bear Lake Dam precipitation station (see Figures 2-28 and 2-29). The isohyet map was adapted from Flint and Martin, 2012 to include contoured bands of precipitation ranges. Precipitation volumes were estimated for each band by multiplying the long-term average for any given band by the area of the band. The average precipitation was then varied year by year based on the annual precipitation totals at the two precipitation stations. Annual precipitation variations in the Big Bear Lake watershed was based on precipitation data at the Big Bear Dam station. Annual precipitation variations in the Baldwin Lake watershed were based on precipitation data at the BBCCSD station. Total annual precipitation between 1990/91 and 2018/19 ranged from approximately 19,400 to 154,300 acre-ft/yr with an average of 68,400 acre-ft/yr (see Column A of Table 2-3a).

Natural Lake Inflow

Surface water inflow to the Bear Valley Basin occurs primarily as a combination of surface water runoff in tributary channels that eventually drain into Big Bear Lake and Baldwin Lake and precipitation falling on the lake surfaces (see Columns B and C of Table 2-3a). Inflow into Big Bear Lake is estimated and reported by BBMWD. For years 1990/91 to 2018/19, annual surface water inflow to Big Bear Lake ranged from 1,717 to 48,613 acre-ft/yr with an average of 14,385 acre-ft/yr. Values for the natural inflow to Baldwin Lake are based on the average inflow from a climate/surface water model published in Flint and Martin (2012). The average annual Baldwin Lake inflow was varied from year to year by the ratio between average annual Big Bear Lake inflow and average annual Baldwin Lake inflow.

Water Supply from Wells

Groundwater pumping for municipal supply is conducted by BBLDWP and BBCCSD for the local communities in the Bear Valley Basin. From years 1990/91 to 2018/19, average annual groundwater pumping by BBLDWP was 2,537 acre-ft/yr and average annual pumping by BBCCSD was 623 acre-ft/yr (see Columns D through F of Table 2-3a).

There are numerous private wells throughout the Bear Valley Basin. Assessing groundwater production from these wells is difficult since the Big Bear area is a weekend and vacation destination and many of the homes served by the private wells are not occupied full time. Nevertheless, for estimating purposes, it was assumed that each private well on record served a household and the water use in each household was 53 gallons per capita per day, based on the five year average per capita water use in the BBLDWP service area (BBLDWP, 2020). There are 583 private wells in the Bear Valley Basin documented from CDWR driller's logs. Assuming three persons per household, the average annual private well groundwater production was estimated to be 105 acre-ft/yr.

Spring Flow

A separate accounting of spring flow for the Green Spot Spring and Van Dusen Slant Wells is shown in Table 2-3, Column G, as provided by BBCCSD. Spring flow from these sources has historically ranged from 81 to 289 acre-ft/yr with an annual average of 190 acre-ft/yr. Spring flow is also captured by BBLDWP but is accounted for in the water supply from wells (Column E of Table 2-3a).

2.6.1.2 Surface Water Outflow

Areal Recharge from Precipitation

Areal recharge from precipitation falling on the valley floor was based on a surface water model of the Big Bear Lake and Baldwin Lake surface water drainage basins (Flint and Martin, 2012). The analysis estimated that approximately 7.5 percent of precipitation falling within the combined Big Bear Lake and Baldwin Lake watersheds becomes groundwater recharge (Table 13 of Flint and Martin, 2012). When applied to annual precipitation, the resulting annual groundwater recharge from areal precipitation for the period 1990/91 to 2018/19 ranged from approximately 1,500 acre-ft/yr to 11,600 acre-ft/yr with an average of approximately 5,100 acre-ft/yr (see Column H of Table 2-3b).

Lake Evaporation

Evaporation of surface water in Big Bear Lake is estimated and reported by BBMWD. For years 1990/91 to 2018/19, annual surface water evaporation in Big Bear Lake ranged from approximately 9,000 acre-ft/yr to 12,500 acre-ft/yr with an average of approximately 11,000 acre-ft/yr (see Column I of Table 2-3b). Values for evaporation of surface water in Baldwin Lake are based on the average evaporation used in the climate/surface water model published in Flint and Martin (2012), which was 3,342 acre-ft/yr (see Column J of Table 2-3b).

Tributary Channel Infiltration

During precipitation events, a portion of the runoff that collects in ephemeral soft bottomed streams on the perimeter and within the Bear Valley Basin infiltrates into the subsurface to become groundwater recharge. There are no data from which to make estimates of this recharge. As this is the least known element of the surface water budget, it was adjusted to balance the inflows and outflows. The resulting average annual tributary channel infiltration for the water budget period of record is approximately 730 acre-ft/yr (see Column K of Table 2-3b).

Return Flow

A portion of water applied to the land surface for landscape irrigation infiltrates past the roots zones of the plants and becomes groundwater recharge. Estimates of the volume of applied water that become groundwater recharge are a function of the volume of water used outdoors and an assumption regarding the percentage of applied water that becomes deep percolation. To estimate the percentage of water used outdoors, TH&Co compared estimates of water deliveries to customers in the BBLDWP and BBCCSD to influent measurements at the BBARWA treatment plant. The difference between the volume of water delivered to customers and the inflow to the plant was assumed to be water used outdoors. For BBLDWP, 35 percent of delivered water was

assumed to be used outdoors. For BBCCSD, 10 percent of delivered water was assumed to be used outdoors. Of the outdoor water use, 25 percent was assumed to become deep percolation and groundwater recharge. Average annual combined return flow from the two water purveyors in the Bear Valley Basin for the period from 1990/91 to 2018/19 was 218 acre-ft/yr (see Column L of Table 2-3b).

System Losses

A portion of the total groundwater pumped and delivered by BBLDWP and BBCCSD is lost in transit between the wells and the homes. BBLDWP has tracked pipeline losses over time, which have ranged from approximately 13 percent prior to 1997 to less than 10 percent after 2008. For BBCCSD, a loss rate of 10 percent was assumed. Based on these assumptions, the average annual system loss in the Bear Valley Basin for the 1990/91 to 2018/19 period was 327 acre-ft/yr (see Column M of Table 2-3b).

Evapotranspiration

Evapotranspiration (ET) is the loss of water to the atmosphere from free-water evaporation, soil-moisture evaporation, and transpiration by plants (Fetter, 1994). Evapotranspiration of precipitation is assumed to be the balance between total precipitation and areal recharge and is associated with native vegetation. From water years 1990/91 to 2018/19, evapotranspiration of precipitation was estimated to average approximately 63,000 acre-ft/yr (see Column N of Table 2-3b).

Big Bear Lake Withdrawals

Local ski resorts periodically withdraw water from Big Bear Lake for snow making. For years 1990/91 to 2018/19, annual withdrawals from Big Bear Lake, as provided by the BBMWD, ranged from approximately 200 acre-ft/yr to 750 acre-ft/yr with an average of approximately 440 acre-ft/yr (see Column O of Table 2-3b).

Releases at Bear Valley Dam

The BBMWD releases water from Big Bear Lake at the dam for downstream irrigation demands. For years 1990/91 to 2018/19, annual releases at the dam, as provided by the BBMWD, ranged from zero to approximately 17,500 acre-ft/yr with an average of approximately 2,400 acre-ft/yr (see Column P of Table 2-3b).

BBARWA Discharges to Lucerne Valley

Treated effluent from the BBARWA treatment plant is exported out of the Bear Valley Basin to a discharge site in Lucerne Valley, approximately 12 miles to the north. Based on data provided by BBARWA, annual discharges to Lucerne Valley during the 1990/91 to 2018/19 period have ranged from 1,892 acre-ft/yr to 4,008 acre-ft/yr with an average of 2,684 acre-ft/yr (see Column Q of Table 2-3b).

2.6.2 Groundwater Budget

The groundwater budget describes the sources and estimates the volumes of groundwater inflow and outflow within the Bear Valley Basin (see Table 2-4). A fundamental premise of the groundwater budget is the following relationship:

$$\text{Inflow} - \text{Outflow} = +/- \Delta S$$

Inflow terms include areal recharge from precipitation, recharge in tributary channels, return flow, and water distribution system losses. It is noted that many of the groundwater inflow terms are surface water outflow terms from Table 2-3. Outflow terms include groundwater pumping and evapotranspiration. The difference between the sum of inflow terms and the sum of outflow terms is the change in groundwater storage (ΔS) (see Table 2-4).

2.6.2.1 Sources of Groundwater Recharge

Areal Recharge

Areal recharge from precipitation falling on the valley floor is estimated to be approximately 7.5 percent of precipitation falling within the combined Big Bear Lake and Baldwin Lake watersheds as described in Section 2.3.1.2. Annual groundwater recharge from areal precipitation for the period 1990/91 to 2018/19 ranged from approximately 1,500 acre-ft/yr to 11,600 acre-ft/yr with an average of approximately 5,100 acre-ft/yr (see Column A of Table 2-4).

Tributary Channel Infiltration

During precipitation events, a portion of the runoff that collects in ephemeral soft bottomed streams on the perimeter and within the Bear Valley Basin infiltrates into the subsurface to become groundwater recharge, as described in Section 2.3.1.2. The average annual tributary channel infiltration for the water budget period of record is estimated to be approximately 730 acre-ft/yr (see Column B of Table 2-4).

Return Flow

A portion of water applied to the land surface for landscape irrigation infiltrates past the roots zones of the plants and becomes groundwater recharge, as described in Section 2.3.1.2. Average annual combined return flow from the two water purveyors in the Bear Valley Basin for the period from 1990/91 to 2018/19 was 218 acre-ft/yr (see Column C of Table 2-4).

System Losses

A portion of the total groundwater pumped and delivered by BBLDWP and BBCCSD is lost in transit between the wells and the homes, as described in Section 2.3.1.2. The average annual system loss in the Bear Valley Basin for the 1990/91 to 2018/19 period was 327 acre-ft/yr (see Column D of Table 2-4).

2.6.2.2 Sources of Groundwater Discharge

Municipal Groundwater Pumping

Groundwater pumping for municipal supply is conducted by BBLDWP and BBCCSD for the local communities in the Bear Valley Basin, as described in Section 2.3.1.1. From years 1990/91 to 2018/19, average annual groundwater pumping by BBLDWP was 2,537 acre-ft/yr and average annual pumping by BBCCSD was 623 acre-ft/yr (see Columns E and F of Table 2-4).

Private Groundwater Pumping

Groundwater production from private wells in the Bear Valley Basin was estimated to be approximately 105 acre-ft/yr, as described in Section 2.3.1.1 (see Column G of Table 2-4).

Evapotranspiration

Evapotranspiration directly from the groundwater occurs in areas where groundwater is shallow enough to support riparian vegetation. The areas identified as groundwater dependent ecosystems on Figure 2-26 were assumed to be areas of groundwater ET. The annual ET rate of 52.6 inches was obtained from the CIMIS station at the Big Bear Lake Golf Course in the Rathbone Subunit. Multiplying the ET rate by the area of riparian vegetation (approximately 247 acres) results in an average annual ET of 1,071 acre-ft/yr. The ET was varied by year in proportion to changes in areal recharge from precipitation. The changes in annual ET reflect the ratio between the long-term average annual recharge from precipitation (5,128 acre-ft/yr) and long-term average annual ET (1,071 acre-ft/yr) (see Column H of Table 2-4).

2.6.3 Changes in Groundwater Storage

Comparison of the groundwater inflow elements of the water budget with the outflow elements shows a cumulative change in groundwater storage over the period between 1990/91 to 2018/19 of approximately 60,000 acre-ft (see Table 2-4; Figure 2-25). The average annual change in storage resulting from the groundwater budget is approximately 2,100 acre-ft/yr.

2.6.4 Overdraft

The average annual change in groundwater storage over the period from 1990/91 to 2018/19, which approximates average hydrologic conditions within the Bear Valley Basin, was approximately 2,100 acre-ft/yr. As the average annual change in storage is positive, there is no overdraft of the groundwater basin. The findings from the groundwater budget are consistent with groundwater level trends in monitoring wells in the basin that show groundwater levels recovering to historical high conditions during periods of above normal precipitation (see Figures 2-17 through 2-24).

2.6.5 Water Year Type

All water budget elements and change in groundwater storage presented herein are based on a water year, which begins October 1 and ends September 30. Water year types with respect to hydrologic conditions (i.e. above average, average or below average precipitation conditions based on Figures 2-28 and 2-29) are shown in the historical water budget tables (Tables 2-3 and 2-4).

2.6.6 Sustainable Yield

Sustainable yield is defined in the Sustainable Groundwater Management Act (SGMA) Chapter 2, §10721 (v) as:

The maximum quantity of water, calculated over a base period representative of long-term conditions in the basin and including any temporary surplus, that can be withdrawn annually from a groundwater supply without causing an undesirable result.

The Sustainable Yield of the Bear Valley Basin is a function of the overall water balance of the area. Changes in surface water/groundwater inflow to the basin and surface water/groundwater outflow from the basin impact the Sustainable Yield. A generalized expression of the water balance is as follows:

$$\text{Inflow} - \text{Outflow} = +/- \text{ Change in Storage} \qquad (1)$$

The water balance equation for pre-developed conditions (prior to human occupation) can be further expressed as:

$$(I_{pr} + I_{str} + I_{mb}) - O_{et} = \Delta S \qquad (2)$$

Where:

I_{pr} = Inflow from Areal Recharge of Precipitation

I_{str} = Inflow from Infiltration of Runoff in Stream Beds

I_{mb} = Inflow from Mountain-Block Recharge

O_{et} = Evapotranspiration

ΔS = Change in Groundwater Storage

It is noted that the Bear Valley Basin is assumed to be closed such that there is no subsurface inflow to the basin or subsurface outflow from the basin. Under pre-developed conditions, the groundwater basin would be in a state of equilibrium such that the inflow and outflow would balance and there would be no significant long-term change in storage assuming a static climatic condition. Under this condition, groundwater levels would be relatively stable.

Underdeveloped land use conditions, the water balance changes as groundwater is pumped from the basin for municipal supply. Some of the pumped groundwater used for irrigation infiltrates past the roots of the plants and returns to the groundwater as return flow. Water distribution system losses is another source of recharge to the groundwater underdeveloped land use conditions.

The water balance equation for developed land use conditions can be modified as follows:

$$(I_{pr} + I_{str} + \mathbf{I_{rfgw}} + \mathbf{I_{sl}} + I_{mb}) - (O_{et} + \mathbf{O_p}) = \Delta S \qquad (3)$$

Where:

I_{rfgw} = Inflow from Return Flow of Applied Water from Groundwater Pumping

I_{sl} = Inflow from Water Distribution System Losses

O_p = Outflow from Groundwater Pumping

If the inflow terms exceed the outflow terms, then the groundwater in storage increases (become positive) and groundwater levels rise. If the outflow terms exceed the inflow, then the groundwater in storage decreases (become negative) and groundwater levels drop. It is assumed that the

Sustainable Yield of the Bear Valley Basin is the long-term average groundwater pumping rate, under projected land use conditions, that results in no significant long-term net negative change in groundwater storage in the basin. Based on this premise, the water balance equation can be rearranged and simplified to estimate Sustainable Yield:

$$\text{Sustainable Yield} = \Delta S + O_p \qquad (4)$$

Thus, if the change in groundwater storage over the planning period is zero then the Sustainable Yield is equal to the pumping. This relationship is valid if the following conditions are met:

1. The Sustainable Yield incorporates a hydrology that is representative of a relatively long period of record that includes multiple wet and dry hydrologic cycles.
2. The land use conditions are representative of the time period.

The Sustainable Yield can also be expressed as all components of the water balance not explicitly expressed in Equation 4:

$$\text{Sustainable Yield} = I_{pr} + I_{str} + I_{rfgw} + I_{mb} \qquad (5)$$

Applying Equations 4 and 5 to the historical water budget of the Bear Valley Basin results in a Sustainable Yield of approximately 5,300 acre-ft/yr.

2.6.7 Current Water Budget

The surface water and groundwater budget for the Bear Valley Basin for the most recent water year with available data (2018/19) is shown in Tables 2-3 and 2-4. Total groundwater inflow to the basin for water year 2018/19 was approximately 9,400 acre-ft. Total groundwater outflow from the basin for the same water year was approximately 4,500 acre-ft. The net change in storage during the water year was approximately 4,900 acre-ft.

2.6.8 Historical Water Budget

The historical surface water and groundwater budgets for the Bear Valley Basin are shown in Tables 2-3 and 2-4 and described in Sections 2.3.1 and 2.3.2. Except for spring flow capture, there are no surface water supplies, imported or otherwise, available to the Bear Valley Basin. Water purveyors in the basin are reliant solely on groundwater. While groundwater production within the basin has never exceeded the long-term Sustainable Yield, the availability of groundwater supplies to meet local water demands is dependent on precipitation cycles. During an extended dry period between 1998 and 2004, groundwater levels dropped creating concern that, if allowed

to continue, would result in impacts to BBLDWP's and BBCCSD's infrastructure. As a result, both agencies implemented water conservation programs for their respective service areas that were successful at reducing water demand and associated groundwater pumping. Groundwater levels recovered in the 2004/05 water year because of significant above-average precipitation, but the agencies have continued with water conservation measures to ensure that groundwater levels would be sufficiently recovered before subsequent dry periods. The conservation and reduced groundwater production have been successful at maintaining acceptable operational groundwater levels, even during the historically dry period from 2011 to 2017.

2.6.9 Projected Water Budget

A projected water budget for the Bear Valley Basin has been developed to incorporate planned increases in groundwater production as well as projects and management actions for maintaining sustainability. The projection also incorporates adjustments to ET to account for potential climate change. The projected surface water and groundwater budgets are shown in Tables 2-5 and 2-6.

Climate adjustments were applied to the precipitation, ET, and lake inflows in the surface water budget based on output from the CDWR's CalSim-II model, which provided adjusted historical hydrology for major drainages and imported supplies based on scenarios recommended by the CDWR Climate Change Technical Advisory Group.[1] The historical proxy time periods selected for the Bear Valley Basin projected water budget were 1991 to 2010 for 2021 to 2040 and 1981 to 2010 for 2041 to 2070. Climate change benchmark factors were assigned at two times within the SGMA planning horizon:

1. A 2030 central tendency time period, which provides near-term projections of potential climate change impacts on hydrology, centered on the year 2030, and
2. A 2070 central tendency time period, which provides long-term projections of potential climate change impacts on hydrology, centered on the year 2070.

Adjustments to future precipitation and ET projections based on the 2030 central tendency time period were applied to the period 2021 through 2040. The central tendency precipitation change factor for this period is 0.971. Change factors for 2020 through 2029 and 2031 through 2040 were linearly decreased based on a linear regression from 1 (2020) and 0.971 (2030). The central tendency ET change factor is 1.04. The change factor for 2020 through 2029 and 2031 through 2040 were linearly decreased as described for precipitation.

[1] DWR Climate Change Technical Advisory Group, 2015. Perspectives and Guidance for Climate Change Analysis. DWR Technical Information Record.

Adjustments to future precipitation and ET projections based on the 2070 central tendency time period were applied to years 2041 through 2070. The precipitation change factor for this time period is 0.939 and the ET change factor is 1.04. Change factors for 2041 through 2070 were based on a linear regression from the 2040 interpreted change factor and the 2070 central tendency value.

Application of the climate adjustments to the future water budgets results in a reduction of Sustainable Yield in the Bear Valley Basin over the 50-year SGMA planning horizon. In comparison to the historical Sustainable Yield of 5,300 acre-ft/yr, the forecasted Sustainable Yield for the 2020 to 2040 time period is estimated to reduce to 5,100 acre-ft/yr (see Figure 2-30). Further into the future, the Sustainabile Yield is forecast to reduce to 4,300 acre-ft/y during the 2040 to 2070 time period.

2.7 Management Areas

The water agencies within the Bear Valley Basin have historically managed their groundwater resources in the context of the eleven hydrologic subunits and one tributary subarea shown on Figures 2-4 and 2-30. Each of these hydrologic subunits and the Lake Williams Tributary Subarea will be considered management areas for the purpose of this GSP.

2.7.1 Criteria for Management Areas

The management areas in the Bear Valley Basin have been created to account for the varying geology, hydrogeology, and water resources across the basin. Although the hydrologic subunits on which the management areas are based were originally defined based on surface water drainage divides, each represents a unique set of geological and hydrogeological characteristics, which impact the availability of water resources within the areas. The management areas and their unique characteristics are described as follows:

Big Bear Lake Watershed

Grout Creek – Groundwater production from this management area serves the community of Fawnskin. While it is within the BBLDWP service area, the infrastructure is completely disconnected from the infrastructure in the main part of BBLDWP's service area south of Big Bear Lake. As such Fawnskin is self-sustained by local water supplies, which consist of a combination of captured spring flow (Cedar Springs), groundwater from the alluvial aquifer system (Seminole Well), and groundwater from the fractured bedrock aquifer (Cherokee Well). The sustainable yield of this management area has been previously estimated to be 280 acre-ft/yr (Geoscience, 2006).

North Shore – Groundwater production from wells in this management area serve a local mobile home park. Water supply to this small community is self-sustained by two wells within the park. The sustainable yield of this management area has been previously estimated to be 170 acre-ft/yr (TH&Co, 2010a).

Gray's Landing – The Gray's Landing management area is a 765-acre area on the west side of Big Bear Lake where granitic bedrock outcrops at the land surface throughout almost the entire area. There is a thin strip of alluvial sediments along the margin of Big Bear Lake where some private wells have been identified. However, no municipal groundwater production occurs from this management area.

Mill Creek – No municipal groundwater production currently occurs in the Mill Creek management area due to groundwater quality issues (uranium). Some private wells are known to be in this area. Future development of the groundwater resources of this area may occur in the future but will depend on wellhead treatment to address the water quality. The sustainable yield of this management area has been previously estimated to range from approximately 150 to 430 acre-ft/yr (Geoscience, 2006; Flint and Martin, 2012).

Village – The subsurface beneath this management area consists predominantly of clay and the thin aquifers from which groundwater is produced have limited natural recharge. This management area is separated hydrologically from the adjacent Mill Creek management area to the west by a granitic bedrock outcrop and the subsurface sediments were deposited in a different environment than the more channelized and permeable sediments of the Rathbone management area to the east. The sustainable yield of this management area has been previously estimated to be 250 acre-ft/yr (Geoscience, 2006).

Rathbone – The subsurface sediments in this management area are characterized by narrow sand channels of Rathbun Creek and Sand Canyon bounded by less permeable alluvium in the southern portion grading to increasing silt and clay deposits in the northern portion associated with low energy mountain meadow deposits. Water supply from this management area includes a combination of captured spring flow from the Dogwood Springs and groundwater production from eight active municipal wells and numerous private wells. The sustainable yield of this management area has been previously estimated to be 1,100 acre-ft/yr (Geoscience, 2006).

Division – Groundwater production in this management area occurs from both the upper and middle aquifer system. In the southern portion of the area, the BBLDWP's McAlister Well produces groundwater from the middle aquifer. In the northern part of the subunit, BBLDWP's Division well field produces groundwater primarily from the middle aquifer, but some wells produce groundwater periodically from the upper aquifer during periods of high groundwater levels. The sustainable yield of this management area has been previously estimated to be between 500 and 600 acre-ft/yr (TH&Co, 2010a).

Baldwin Lake Watershed

West Baldwin – This management area covers approximately 2,780 acres and includes Sawmill Canyon on the south and extends to the north to include a significant portion of the basin between Baldwin Lake and Big Bear Lake (see Figure 2-30). Most of BBCCSD's groundwater production for municipal supply occurs in this subunit. BBLDWP has one well in the Sawmill Canyon area, which is planned to be pumped in the future. Almost all groundwater production is from the middle aquifer although some wells are perforated into the lower aquifer. Groundwater quality in the lower aquifer is impacted by naturally occurring fluoride that exceeds the MCL. The sustainable yield of this management area has been previously estimated to be between 150 and 1,000 acre-ft/yr (Geoscience, 1999; Flint and Martin, 2012).

Erwin – The Erwin Management Area covers approximately 8,460 acres in the southeast portion of the Baldwin Lake watershed. Principal surface water features include Fish Hatchery Spring, Green Spot Spring, Shay Creek, Shay Pond, and Erwin Lake. Groundwater is produced primarily out of the middle aquifer and periodically out of the upper aquifer when groundwater levels are shallow. Spring flow from Green Spot Spring is captured for municipal supply. The sustainable yield of this management area has been previously estimated to be approximately 900 acre-ft/yr (Geoscience, 2006).

Lake Williams – The Lake Williams Tributary Subarea of the Erwin Hydrologic Subunit has been identified as a separate management area because it is, for the most part, hydrologically separated from the Erwin Management Area (see Figure 2-30). The Lake Williams Management Area covers approximately 1,226 acres in the southeast part of the Erwin Hydrologic Subunit. The BBLDWP serves the Lake William community, which is isolated from the infrastructure in the rest of BBLDWP's service area. As such, Lake William is self-sustained by local water

supplies, which consist solely of groundwater pumped from the alluvial aquifer system. The sustainable yield of this management area, which includes the Lake William Tributary Subarea and the Arrastre Creek Subarea, is estimated to be approximately 545 acre-ft/yr (Geoscience, 2004c; TH&Co, 2010b).

East Baldwin - The East Baldwin Management Area covers approximately 5,014 acres of the eastern portion of the Baldwin Lake watershed. This management area includes almost all of Baldwin Lake, which is the primary surface water feature. Most of the groundwater production in this management area is from private wells. The BBCCSD operates one well (Well 8) in the western part of the management area. The sustainable yield of this management area has been estimated to be approximately 170 acre-ft/yr (Flint and Martin, 2012).

Van Dusen – The Van Dusen management area covers approximately 4,345 acres of the northwestern part of the Baldwin Lake watershed. This management area is within the Bear Valley Basin GSA but outside of the Bear Valley Basin as defined by the CDWR. Aside from a relatively narrow band of alluvium along the Van Dusen Canyon drainage, the entire management area consists of bedrock. It is included as a management area because the BBCCSD captures water via a couple of slant wells in this area. The Van Dusen Canyon has also been investigated as a potential area for artificial recharge (Geoscience, 2004a). The sustainable yield of this management area has been estimated to be approximately 760 acre-ft/yr (Flint and Martin, 2012).

2.7.2 Monitoring Plan

A network of groundwater monitoring wells has been identified to enable the collection of groundwater levels and groundwater quality necessary to inform decisions with respect to the sustainability of the Bear Valley Basin (see Figure 2-31). Groundwater monitoring wells have been selected for each management area except Gray's Landing and Van Dusen, where no significant groundwater production is currently occurring. A detailed description of the monitoring network and monitoring plan, including data collection protocols and monitoring frequency, is provided in Section 3.5 of this GSP. The monitoring plan also includes an assessment of data gaps and a data management plan.

A subset of groundwater level monitoring features in the monitoring plan have been identified as representative monitoring sites to be relied on for the purpose of assessing progress with respect to groundwater level sustainability in the basin. The representative groundwater level monitoring sites are summarized in Table 2-7 and shown on Figure 2-31. At least one representative groundwater level monitoring site has been identified within the ten currently active management

areas. Where possible based on available wells, representative monitoring sites have been chosen with perforations exclusively in either the Middle or Lower Aquifer.

2.7.3 Coordination with Adjacent Areas

The Bear Valley Basin is an isolated, closed basin with no significant hydrologic interaction with other basins identified in CDWR Bulletin 118. The basin will be managed by one GSA, the BVBGSA. As such, coordination with adjacent basins will not be necessary.

Many of the management areas are relatively isolated hydrologically from one another and groundwater production from one has little impact on the other, despite being in relative proximity (e.g. Grout Creek, North Shore, Gray's Landing, Mill Creek, Village, Rathbone, Van Dusen, and Lake William). Minimum thresholds for the Management Areas that have the potential to be hydrologically connected to adjacent Management Areas have been selected such that, if exceeded, would not cause undesirable results in one or the other. These Management Areas include Division, West Baldwin, Erwin and East Baldwin.

Management of the Bear Valley Basin is adaptive. As management actions and projects are implemented throughout the basin and as additional data are collected through the Bear Valley Basin Monitoring Plan, minimum threshold values and measurable objectives may change. Changes to basin management to address undesirable results will be conducted through the BVBGSA.

Summary of Aquifer Properties

State Well Number	DWR Number or Well Name	Well Owner	Perforation Interval	Total Perforation Length (ft)	Year of Pumping Test	Pumping Test Type	Pumping Duration (hours)	Specific Capacity (gpm/ft)[1]	Transmissivity (gpd/ft)[2]	Hydraulic Conductivity (ft/day)[3]	Storativity

Summary of Active Cleanup Sites Within the Bear Valley Basin

Geotracker Global ID	Site Type	Status	Constituent of Concern
80000973	DTSC Cleanup Site	Inactive - Needs Evaluation	NA
L10007155213	Land Disposal Site	Open - Closed/With Monitoring	None
T0607100630	LUST Cleanup Site	Open - Inactive	Gasoline, MTBE, TBA, other fuel oxygenates
T0607100283	LUST Cleanup Site	Open - Remediation	Gasoline, MTBE, TBA, other fuel oxygenates
T0607145144	LUST Cleanup Site	Open - Inactive	Gasoline, MTBE, TBA, other fuel oxygenates
T0607100237	LUST Cleanup Site	Open - Site Assessment	Gasoline
T0607124341	LUST Cleanup Site	Open - Site Assessment	Gasoline
T0607100236	LUST Cleanup Site	Open - Remediation	Gasoline
T0607100176	LUST Cleanup Site	Open - Eligible for Closure	Gasoline

Notes:

LUST = Leaking underground storage tank
DTSC = Department of Toxic Substances
MTBE = Methyl tert-butyl ether
TBA = Tertiary Butyl Alcohol

Notes:

[A] Estimated based on annual precipitation rates from the Big Bear Lake Dam and Big Bear City Community Services District precipitation stations.

[B] Losses reported by BBLDWP. Losses for BBCCSD assumed to be 10%.

[C] Estimated based on per capita water use. Assumes three people per household.

									Cumulative Change in Storage:		36,453

Notes:

[A] Estimated based on annual precipitation rates from the Big Bear Lake Dam and Big Bear City Community Services District precipitation stations.

[B] Losses reported by BBLDWP. Losses for BBCCSD assumed to be 10%.

[C] Estimated based on per capita water use. Assumes three people per household.

Summary of Representative Monitoring Sites (RMS)

Watershed	Management Area	Well Name	RMS Well	X Coordinate (UTM83)	Y Coordinate (UTM83)	Perforation Interval	Aquifer Monitored	Period of Historical Record
Big Bear Lake	Grout Creek	Cherokee Well	Yes	504836.77	3791997.54	130-590	Middle	2013 - 2019

3. Sustainable Management Criteria

3.1 Introduction

This section describes the conditions that constitute sustainable groundwater management for the Bear Valley Basin. Sustainable groundwater management will be evaluated in the context of the sustainability goal for the basin and the absence of undesirable results. Undesirable results are evaluated for each of the sustainability indicators specified in SGMA:[2]

- Chronic lowering of groundwater levels indicating a depletion of supply if continued over the planning and implementation horizon;
- Reduction of groundwater storage;
- Seawater intrusion;
- Degraded water quality, including the migration of contaminant plumes that impair water supplies;
- Land subsidence that substantially interferes with surface land uses; and
- Depletions of interconnected surface water that have adverse impacts on beneficial uses.

When impacts associated with any one of the sustainability indicators become significant and unreasonable across the basin, it is considered an undesirable result.

It is noted that the Bear Valley Basin is isolated in the San Bernardino Mountains and not in hydrologic connection with any neighboring basins. As such, the sustainable management criteria identified herein will not result in groundwater impacts to other designated groundwater basins identified in CDWR Bulletin 118.

3.2 Sustainability Goal

The sustainability goal of the Bear Valley Basin (BVB) is the absence of undesirable results associated with groundwater pumping through a collaborative, basin-wide program of groundwater management. In adopting this GSP, it is the express goal of the BVBGSA to balance the needs of all groundwater users in the Bear Valley Basin within the sustainable limits of the basin's resources, while maintaining the unique cultural, community, and business aspects of the Bear Valley Basin.

3.3 Process for Establishing Sustainable Management Criteria

The Sustainable Management Criteria (SMC) discussed and established in this Section were developed in consultation with BVBGSA's member agencies, local stakeholders, technical leads,

[2] California Water Code, Division 6, Section 10721; Definitions x. Undesirable Result

and other interested parties. The general process leading up to the development and establishment of these SMC included:

- Reviewing existing hydrogeologic data assembled in the Bear Valley Basin Setting (Section 2).
- Corresponding with BVBGSA members and their staff to identify groundwater levels that would present undesirable results for the Bear Valley Basin and its individual management areas;
- Holding public workshops outlining the process for GSP development, discussing SMC, and providing data and context related to local groundwater-related issues; and
- Soliciting public feedback through public comment, stakeholder surveys, and written correspondence, to gather information on local values, locally relevant groundwater issues, and how local stakeholders might define groundwater conditions that they consider to be undesirable.

3.4 Sustainable Management Criteria

3.4.1 Chronic Lowering of Groundwater Levels

While groundwater levels in the Bear Valley Basin fluctuate seasonally and with prolonged wet and dry hydrologic periods, sustained lowering of groundwater levels below the minimum thresholds in any given management area is considered an undesirable result (see Section 3.4.1.5).

3.4.1.1 Information Used to Establish Measurable Objectives and Minimum Thresholds

Information and data used to establish measurable objectives and minimum thresholds related to groundwater levels included:

- Historical groundwater elevation data measured in wells monitored by BVBGSA managers.
- Information on the constructed depths and perforated intervals of production wells.
- Input from basin managers and stakeholders regarding preferred current and future operational groundwater elevations as well as groundwater levels that potentially could result in significant and unreasonable conditions.

3.4.1.2 Locally Defined Significant and Unreasonable Conditions

Significant and unreasonable groundwater levels in the Basin are those that:

- Reduce the pumping capacity of existing municipal wells to the point that they are no longer adequate to meet water demands.
- Cause significant financial burden to those who rely on the groundwater basin.
- Trigger other SGMA sustainability indicators (e.g. water quality, land subsidence, etc.).

3.4.1.3 Measurable Objectives

In the Bear Valley Basin, groundwater levels in most management areas are currently sustainable with conservation measures and support the water demands of both private and public stakeholders. As such, groundwater level Measurable Objectives have been selected at each Representative Monitoring Site (RMS) at the average 2019 groundwater level at that site. Representative Monitoring Sites are shown on Figure 2-31. Measurable Objectives for each RMS well are shown on Figures 3-1 through 3-10. Sustainable Management Criteria for each RMS well by management area are summarized in Table 3-1.

Groundwater pumping within the Basin, as a whole, has historically been within the Sustainable Yield resulting in relatively stable long-term groundwater levels. While there have periodically been localized groundwater level declines, pumping sustainability has been maintained through changes in pumping distribution between management areas and implementation of conservation measures. The BVBGSA plans to maintain pumping sustainability through continued managed pumping and conservation while allowing for strategic growth of the valley.

3.4.1.4 Interim Milestones

As the recent groundwater conditions are the same as the measurable objective, the interim milestones and measurable objectives are the same at most of the RMS wells (see Figures 3-1 through 3-10). At RMS wells in the Rathbone (Sand Canyon Well), Erwin (Maple Well), and North Shore (RV Park Well No.1), allowance is made for slightly lower interim milestones to allow for some fluctuation in groundwater levels during the sustainability transition period between 2022 and 2042.

3.4.1.5 Minimum Thresholds

As defined in Section §354.28(c)(1) of the SGMA regulations, "*The minimum threshold for chronic lowering of groundwater levels shall be the groundwater elevation indicating a depletion of supply at a given location that may lead to undesirable results.*" In general, the groundwater level minimum threshold was set, for any given RMS, at the depth/elevation at which it would become difficult for the local water supply municipality to produce groundwater in amounts historically necessary to meet municipal supplies. Minimum Thresholds for each RMS well are shown on Figures 3-1 through 3-10.

Minimum Thresholds are locally defined, in the sense that localized geological, hydrogeological, and hydrological conditions affected their selection. For example, in the Grout Creek Management Area, the Cherokee Well RMS is approximately 600 feet deep and perforated in granitic bedrock. The Seminole Well RMS, on the other hand, is only 65 feet deep and perforated in the alluvial aquifer. Even though these RMS wells are only 550 feet apart, their Minimum Threshold groundwater elevations are significantly different due to differences in well construction and source aquifers (it is noted that the Cherokee Well is the only RMS in the Bear Valley GSP that is constructed in bedrock).

Each management area is relatively distinct hydrologically and, in most cases, hydrogeologically. Accordingly, Minimum Threshold exceedances in one area are not anticipated to contribute to Minimum Threshold exceedances in neighboring management areas. In those cases where groundwater level impacts are determined to extend across multiple management areas, groundwater pumping distribution can be adjusted to mitigate the impacts.

3.4.1.6 Relationship of Groundwater Level Sustainable Management Criteria to Other Sustainability Indicators

Groundwater elevation SMC can influence the other sustainability indicators.

Change in groundwater storage. Changes in groundwater elevations result in changes in the amount of groundwater in storage. Pumping at or less than the Sustainable Yield will maintain average groundwater elevations in the basin. The goal of the BVBGSA is to maintain average groundwater elevations near the measurable objectives but above the minimum thresholds through the SGMA 50-year planning horizon, consistent with the practice of pumping at or less than the sustainable yield. As groundwater elevations provide an indication of groundwater in storage, maintenance of these levels will not result in a long term significant or unreasonable depletion of groundwater in storage.

Seawater intrusion. Given the Bear Valley Basin's isolated nature in the San Bernardino Mountains and its physical distance from the ocean, seawater intrusion cannot occur in this area. Accordingly, this sustainability indicator is not applicable to this basin.

Degraded water quality. Maintaining groundwater levels protects against degradation of water quality or exceeding regulatory limits for constituents of concern in supply wells. Fluoride concentrations in the discharge from some wells in the eastern portion of the Bear Valley Basin tend to increase when groundwater levels drop as the contribution of water to the wells comes increasingly from the deeper aquifers where the fluoride concentrations are higher. As such, the groundwater level minimum thresholds that have been selected

for wells in the Bear Valley Basin are protective of high fluoride concentrations in the produced groundwater.

Land Subsidence. A significant and unreasonable condition for subsidence is permanent pumping induced subsidence that substantially interferes with surface land use. Subsidence is caused by dewatering and compaction of clay-rich sediments in response to lowering groundwater levels. Very small amounts of recoverable land surface elevation fluctuations have been reported across the Bear Valley Basin. The groundwater elevation minimum thresholds are set below existing groundwater elevations, which are protective of nonrecoverable land subsidence. Should new subsidence be observed due to lower groundwater elevations, the groundwater elevation minimum thresholds will be raised to avoid this subsidence.

Depletion of interconnected surface water. While there is evidence for a connection between groundwater and some surface water bodies in the Bear Valley Basin under high groundwater conditions, the direct impact of low groundwater levels on the beneficial uses of each water body has not been established. In general, the measurable objectives developed for groundwater levels in the vicinity of surface water bodies in Bear Valley Basin have not resulted in significant and unreasonable conditions in the past. Accordingly, the groundwater level SMC used herein serve as a proxy for this sustainability indicator.

3.4.1.7 Undesirable Results

A lowering of groundwater levels below the Minimum Threshold in any one RMS well within any two management areas (not including the Lake Williams management area) for three consecutive months in any two consecutive years constitutes an undesirable result. Lowering of groundwater levels below the Minimum Threshold in the Lake Williams RMS well will require investigation and increased monitoring to determine the relative impact of the exceedance on the BBDWP's ability to meet municipal water supply demands.

3.4.2 Reductions of Groundwater in Storage

3.4.2.1 Information Used to Establish Measurable Objectives and Minimum Thresholds

Information and data used to establish measurable objectives and minimum thresholds related to groundwater storage included:

- Historical groundwater elevation data measured in wells monitored by BVBGSA managers.

- Information on the constructed depths and perforated intervals of production wells.
- Input from basin managers and stakeholders regarding preferred current and future operational groundwater elevations as well as groundwater levels that potentially could result in significant and unreasonable conditions.

3.4.2.2 Locally Defined Significant and Unreasonable Conditions

A significant and unreasonable reduction in groundwater storage in the basin occurs when:

- The pumping capacity of existing municipal wells is reduced to the point that they are no longer adequate to meet water demands.
- It causes significant financial burden to those who rely on the groundwater basin.
- It triggers other SGMA sustainability indicators (e.g. water quality, land subsidence, etc.).

3.4.2.3 Measurable Objectives

As the groundwater storage of the Basin is directly related to groundwater level conditions, the measurable objectives used for chronic lowering of groundwater levels (see Section 3.4.1.3 herein) are applicable to reduction in groundwater storage. The measurable objective, using the groundwater level proxy, is stable average groundwater levels at 2019 conditions.

3.4.2.4 Interim Milestones

As the groundwater storage of the Basin is directly related to groundwater level conditions, the interim milestones used for chronic lowering of groundwater levels (see Section 3.4.1.4 herein) are applicable to reduction in groundwater storage.

3.4.2.5 Minimum Thresholds

Section §354.28(c)(2) of the SGMA regulations states that "*The minimum threshold for reduction of groundwater storage shall be a total volume of groundwater that can be withdrawn from the basin without causing conditions that may lead to undesirable results. Minimum thresholds for reduction of groundwater storage shall be supported by the sustainable yield of the basin, calculated based on historical trends, water year type, and projected water use in the basin.*"

It has been observed that groundwater levels decline in the Basin during dry years when natural recharge is limited and groundwater production exceeds recharge for that year (see Section 2.2.1 of this GSP). The Bear Valley Basin has successfully sustained groundwater production during many historical dry climatic cycles, each consisting of multiple below normal precipitation years. Although the groundwater storage capacity of the Bear Valley Basin is thought to be relatively small compared to other basins in southern California, as indicated by significant fluctuations in

groundwater levels during wet and dry periods, its exact storage capacity is unknown. A preliminary minimum threshold is established as a depletion of 9,000 acre-ft of groundwater in storage in any two-year period, which is a depletion of approximately the sustainable yield each year over two consecutive years. However, as more data are collected, this minimum threshold may be revised.

3.4.2.6 Undesirable Results

A depletion of storage by more than 9,000 acre-ft in any consecutive two-year period is anticipated to be an undesirable result, as groundwater levels would likely drop below the minimum thresholds in many RMS wells, potentially triggering the impacts described in Section 3.4.1.5, herein.

3.4.3 Seawater Intrusion

Seawater intrusion cannot occur in the Bear Valley Basin due to its location with respect to the Pacific Ocean. The Bear Valley Basin is an isolated mountain groundwater basin located approximately 70 miles inland of the Pacific Ocean (see Figure 2-1). This mountain aquifer system is separated hydraulically from the coastal aquifers that are susceptible to seawater intrusion. Thus, no sustainable management criteria need be established.

3.4.4 Degraded Groundwater Quality

3.4.4.1 Information Used to Establish Measurable Objectives and Minimum Thresholds

Information and data used to establish measurable objectives and minimum thresholds related to groundwater quality included:

- Historical groundwater quality data measured in wells monitored by BVBGSA managers.
- Input from basin managers and stakeholders regarding meeting future water quality standards and addressing portions of the groundwater basin that are currently unusable due to naturally occurring groundwater quality issues.

3.4.4.2 Locally Defined Significant and Unreasonable Conditions

Locally defined significant and unreasonable conditions were assessed based on federal and state mandated drinking water and groundwater quality regulations, public workshops, and discussions with BVBGSA managers. A significant and unreasonable groundwater quality condition occurs when the water produced from one or more municipal supply wells cannot be used for municipal supply because constituents of concern (COCs) exceed drinking water standards that cannot be mitigated through treatment or blending.

3.4.4.3 Measurable Objectives

The quality of the groundwater in Bear Valley Basin is excellent and, except for isolated areas with naturally occurring COCs, meets regulatory requirements for municipal supply. In those areas where naturally occurring COCs occur, local agencies have been able to beneficially use the water through treatment or blending. The measurable objective for groundwater quality in the Bear Valley Basin is to maintain the existing quality and address high concentrations of naturally occurring water COCs through treatment and/or blending.

3.4.4.4 Minimum Thresholds

Section §354.28(c)(2) of the SGMA regulations states that "*The minimum threshold shall be based on the number of supply wells, a volume of water, or a location of an isocontour that exceeds concentrations of constituents determined by the Agency to be of concern for the basin*."

The primary beneficial use of the groundwater produced from the Bear Valley Basin is municipal supply. The inability to produce groundwater suitable for municipal supply due to groundwater quality is considered an undesirable result. In keeping with State of California and Federal drinking water regulations, the established maximum contaminant levels (MCLs) for the naturally occurring COCs found in the groundwater basin, as described in Section 2.2.4 of this GSP (i.e. fluoride, arsenic, uranium, and manganese) are also the minimum thresholds, given that the groundwater produced from wells cannot be used for municipal supply if any of COC concentrations exceed their respective MCLs.

Historically, the agencies within the Bear Valley Basin have been able to address COC concentrations by perforating new wells to avoid the constituents, treating the water through wellhead treatment, or blending. Fluoride concentrations in the discharge from some wells in the eastern portion of the Basin tend to go up when groundwater levels drop as the contribution of water to the wells comes increasingly from the deeper aquifers where the fluoride concentrations are higher. As such, the groundwater level minimum thresholds that have been selected for wells in the Basin are protective of high fluoride concentrations in the produced groundwater.

Movement of existing point source contaminant plumes resulting from groundwater production management is not anticipated to occur in the Bear Valley Basin. As groundwater levels are not predicted to change significantly into the future, neither are groundwater flow paths that might change the direction of contaminant plume migration.

3.4.4.5 Undesirable Results

Undesirable results for the water quality of the Bear Valley Basin include the following:

- Any reduction in the existing water quality of the Basin resulting from anthropogenic activity including projects and management actions associated with this GSP,
- An exceedance of the MCL for any COC in the discharge of one or more wells such that the groundwater from that well(s) cannot be treated or blended for municipal supply.

On average during any one year, no groundwater quality minimum threshold shall be exceeded as a direct result of projects or management actions taken as part of GSP implementation.

3.4.5 Land Subsidence

3.4.5.1 Information Used to Establish Measurable Objectives and Minimum Thresholds

Historical InSAR data has not detected permanent, non-recoverable land subsidence in the Bear Valley Basin (see Section 2.2.5 of this GSP). Land subsidence is a gradual settling of the land surface caused by compaction of fine-grained subsurface sediments in areas where the groundwater level has been lowered from groundwater pumping. If groundwater levels are kept low enough for a long enough period of time, the ensuing land subsidence can become permanent (i.e. non-recoverable). The primary sources of information to inform sustainable management criteria for land subsidence in the Bear Valley Basin are Flint and Martin (2012) and the California DWR online InSAR dataset.

3.4.5.2 Locally Defined Significant and Unreasonable Conditions

Land subsidence would become significant and unreasonable within the Bear Valley Basin if it was non-recoverable and caused damage to surface land uses such as roads, buildings or other infrastructure. The most vulnerable areas to future land subsidence are the area of the airport and the Big Bear Village, which are areas where there is thick layers of fine-grained clay sediments underground. However, non-recoverable land subsidence has not been observed in these areas and maintenance of groundwater levels above their respective minimum thresholds will be protective of land subsidence in the future.

3.4.5.3 Measurable Objective

Existing ground surface elevation data do not suggest the occurrence of permanent land subsidence in the Basin. Therefore, the measurable objective for subsidence is maintenance of current ground surface elevations.

3.4.5.4 Minimum Threshold

The minimum threshold for land subsidence in the Bear Valley Basin will be no more than 0.1 foot in any single year and a cumulative of 0.5 foot in any five-year period, as measured between June of one year and June of the subsequent year using InSAR.

3.4.5.5 Undesirable Results

Any pumping induced, non-recoverable land subsidence that causes damage to surface infrastructure or other surface land uses is considered an undesirable result.

3.4.6 Depletion of Interconnected Surface Water

3.4.6.1 Information Used to Establish Measurable Objectives and Minimum Thresholds

The potential for interconnection between surface water and groundwater in the Basin occurs in three different areas:

1. Beneath and at the margins of Big Bear Lake
2. Shay Pond in the Erwin Subunit
3. Natural springs fed by bedrock aquifers in the watershed surrounding the Basin

Studies of the relationship between surface water and groundwater at Big Bear Lake and Shay Pond have been conducted and described in Section 2.2.6 of this GSP. Detailed information regarding the historical flow rate of natural springs has been obtained from BBLDWP and BBCCSD. These data and studies were used to inform the sustainable management criteria for the depletion of interconnected surface water in the Basin.

3.4.6.2 Locally Defined Significant and Unreasonable Conditions

Regarding the connection between groundwater levels and surface water in Big Bear Lake and Shay Pond, while there is evidence for a connection between the two under high groundwater conditions, the direct impact of low groundwater levels on the beneficial uses of each water body has not been established. In general, the measurable objectives developed for groundwater levels in the vicinity of Big Bear Lake and Shay Pond have not resulted in significant and unreasonable conditions in the past. Groundwater and surface water monitoring will be required into the future to determine if groundwater levels approaching the minimum thresholds in these areas has an adverse impact on the surface water bodies.

As the spring flow fed by bedrock aquifers at the margins of the Basin is entirely dependent on precipitation, groundwater pumping does not have an impact on this surface water source.

3.4.6.3 Measurable Objectives

Measurable objectives applicable to depletion of interconnected surface water were not developed for the GSP. If in the future, data from the monitoring program allow for development of a relationship between lowered groundwater levels and their impact on surface water bodies, then measurable objectives specific to this sustainability indicator will be developed. In the meantime, groundwater level measurable objectives will serve as a proxy.

3.4.6.4 Minimum Thresholds

Minimum thresholds applicable to depletion of interconnected surface water were not developed for the GSP. If in the future, data from the monitoring program allow for development of a relationship between lowered groundwater levels and their impact on surface water bodies, then minimum thresholds specific to this sustainability indicator will be developed. In the meantime, groundwater level minimum thresholds will serve as a proxy.

3.4.6.5 Undesirable Results

In general, if lowering of groundwater levels in the vicinity of Big Bear Lake and Shay Pond below their historical levels was shown to have a negative impact on the beneficial uses of these water bodies, then that would be considered an undesirable result. Future data collection and monitoring will help quantify the relationship between groundwater levels and surface water levels in these water bodies.

4. Monitoring Network

4.1 Introduction

The groundwater monitoring network presented herein is to be relied on by the BVBGSA to collect the data necessary to prepare its annual reports and assess progress with regard to achieving sustainability goals. Data to be collected from the monitoring network will include groundwater levels, groundwater quality and land elevation data. Groundwater levels and quality data will be collected from a network of monitoring wells spaced throughout the Bear Valley Basin. The monitoring well network includes existing monitoring wells and production wells. Changes in land elevation, in the form of InSAR satellite data, will be obtained from the CDWR website.

4.1.1 Monitoring Objectives

The monitoring network has been selected to meet the following Basin wide objectives:

- To ensure that the data collected within the basin are in sufficient quantities, areal distribution, frequency and accuracy to provide meaningful results for demonstrating progress toward achieving measurable objectives of each GSA and the sustainability goal of the subbasin as a whole.
- To monitor impacts to the beneficial uses and users of groundwater.
- To monitor changes in groundwater conditions relative to measurable objectives and minimum thresholds.
- Enable the quantification of annual changes in water budget components.
- To identify data gaps and monitoring features to address the data gaps.
- To provide a standard methodology for the collection of groundwater and land surface subsidence data within the Basin.
- To provide for a central, secure monitoring database available to the BVBGSA for their use.

The monitoring network and associated monitoring plan is both flexible and iterative, allowing for the addition or subtraction of monitoring features, as necessary, and to accommodate changes in monitoring frequency and alternative methodologies, as appropriate.

4.1.2 Monitoring Plan Organization

The monitoring network enables the collection of the following types of data:

- Groundwater Level Data
- Groundwater Quality Data

- Land Subsidence Data

Each data type will be addressed in its own section that includes a description of the monitoring features for collecting data, the data collection protocols, and the monitoring frequency.

The final section of this section describes the data management system that includes a description of the database management platform, criteria for data QA/QC, file storage, security and access, and database maintenance.

4.2 Chronic Lowering of Groundwater Levels

Monitoring wells to be used to collect groundwater level data are shown on Figure 2-31. This groundwater level monitoring network consists of 37 existing wells located throughout the Basin. At least one monitoring well has been selected for each Management Area except Grays Landing. No groundwater production occurs in the Grays Landing Management Area and, as such, no groundwater level monitoring is conducted. A table of monitoring wells included in the Bear Valley Basin monitoring network is summarized in Table 2-7.

4.2.1 Monitoring Procedure

Groundwater level measurements shall be collected from each well using either a calibrated well sounder or a pressure transducer. Measurement devices will be calibrated to the nearest 0.01 ft. All equipment must be in good working condition. No damaged or refurbished electrical sounding tape shall be used.

Groundwater level measurements must be representative of static (i.e. non-pumping) groundwater level conditions. To ensure measurement of static groundwater levels in active pumping wells, the field technician collecting the data must verify that the pump has been off for at least 24 hours prior to collecting the data.

4.2.1.1 Manual Groundwater Level Measurements

The following monitoring procedure shall be used to obtain manual groundwater level measurements in the field:

- Upon arrival at each site, the field technician shall note the well name, time of day, and date on the standard groundwater level data form (see Appendix A).
- All monitoring equipment shall be cleaned prior to lowering it into the well(s) using the following decontamination procedure:
    - Wash equipment with an Alconox solution which is followed by a deionized water rinse.

  - Triple rinse equipment with deionized water.
  - Place equipment on clean surface such as teflon or polyethylene sheet to air dry.
- To measure the depth to groundwater with an electrical sounder or meter, slowly lower the steel tape or water level electrical tape into the designated sounding port for production wells and into the main well for monitoring wells. Electrical tapes are lowered to the water surface, as determined by the audio signal, meter, or technician. Depths to groundwater are measured relative to the dedicated reference point at the top of the casing or sounding tube. Depth to groundwater shall be immediately recorded on the standard groundwater level data form (see Appendix A). Depths to groundwater shall be compared to previous measurements in the field and re-measured if significantly different.
- When finished sounding the groundwater level, all downhole equipment shall be removed, and where existing, the well cap shall be replaced, and the riser locked.
- Prior to leaving the monitoring well site, the field representative shall note any physical changes in the concrete well pad and riser pipe, such as erosion, cracks or damage. All changes shall be recorded on the standard field forms provided in Appendix A.

4.2.1.2 Automatic Groundwater Level Measurements Using Transducers

Transducers may be installed in monitoring wells identified as representative monitoring sites. Transducers shall be installed below the groundwater level with enough submergence to accommodate anticipated groundwater level fluctuations.

4.2.2 Frequency of Measurement

Groundwater level measurements from the monitoring wells shown on Figure 2-31 will be collected monthly. For those monitoring wells equipped with pressure transducers, the transducer will be programmed to record one groundwater level measurement per day. Pressure transducers will be downloaded on a semi-annual basis. During each download session, the field technician will also obtain a manual groundwater level measurement to verify transducer readings and ensure that the instruments are working properly.

4.3 Reduction in Groundwater Storage

Groundwater level data to be relied on for the change in groundwater storage estimates will be collected as described in Section 4.2 of this GSP. The change in groundwater storage will be estimated using the following equation:

$$V_w = S_y A \, \Delta h$$

Where:

V_w	=	the volume of groundwater storage change (acre-ft).
S_y	=	specific yield of aquifer sediments (unitless).
A	=	the surface area of the aquifer within the Tule Subbasin/GSA (acres).
Δh	=	the change in hydraulic head (i.e. groundwater level) (feet).

The change in storage estimate is specific to the shallow aquifer as the groundwater level in the deep aquifer will not likely drop below the top of the aquifer. The calculations will be made using a Geographic Information System (GIS) map of the Bear Valley Basin that will be discretized into 300-foot by 300-foot grids to allow for spatial representation of specific yield and groundwater level change.

The distribution of specific yield for the shallow aquifer will be based on values obtained from pumping tests conducted on wells in the basin.

For the areal distribution of change in hydraulic head within the Tule Subbasin/GSA, groundwater contours for the spring of the previous year will be digitized and overlain on the grid map of the Bear Valley Basin in GIS. Groundwater levels will then be assigned to each grid. A contour map with groundwater elevation contours from spring of the next year will also be digitized and overlain on the grid map. Change in hydraulic head (groundwater level) at each grid will be calculated as the difference in groundwater level between the two years.

The complete GIS files of specific yield and groundwater levels will be exported into a spreadsheet program for the final analysis of groundwater storage change. The change in groundwater storage will be calculated for each grid cell by multiplying the change in groundwater level by the specific yield and then by the area of the cell.

The data from the analysis can be used to develop change in storage maps for incorporation into the annual reports.

4.4 Seawater Intrusion

Seawater intrusion cannot occur in the Bear Valley Basin due to its location with respect to the Pacific Ocean. The Bear Valley Basin is an isolated mountain groundwater basin located approximately 70 miles inland of the Pacific Ocean (see Figure 2-1). This mountain aquifer system is separated hydraulically from the coastal aquifers that are susceptible to seawater intrusion. As such, monitoring for seawater intrusion is not necessary and is not included in this monitoring plan.

4.5 Degraded Water Quality

The groundwater quality monitoring plan specified in this section is designed to address the primary water quality undesirable result described in the Sustainable Management Criteria (Section 3 of this GSP), which is the inability to produce groundwater suitable for municipal supply. Accordingly, groundwater samples will be collected from agency production wells and analyzed in accordance with their required sampling and analysis schedule specified by the California Division of Drinking Water (DDW).

The groundwater sampling protocols described herein will ensure that:

- Groundwater quality data are collected from the correct location
- Groundwater quality data are accurate and reproducible
- Groundwater quality data represent conditions that inform appropriate basin management decisions
- All salient information is recorded to normalize, if necessary, and compare data
- Data are handled in a way that ensures data integrity

4.5.1 Groundwater Quality Constituents to be Analyzed

Groundwater quality constituents to be analyzed as part of this GSP are the same as are currently being analyzed to comply with California DDW requirements for drinking water. A complete list of the constituents that are currently being analyzed and which are proposed to be analyzed into the future is summarized in Table 4-1. In general, these constituents include general mineral and physical properties (including nitrate), volatile organic compounds (VOCs), methyl tert butyl ether (MTBE), ethylene dibromide (EDB), dibromochloropropane (DBCP), and gross alpha.

4.5.2 Sample Collection Protocol

All samples shall be collected from the discharge point near the well head and placed in laboratory-prepared sample containers. Groundwater samples will be collected during normal operation of the well to ensure that the samples are reflective of groundwater quality and not stagnant water in the well. The technician collecting the sample shall wear new latex or neoprene gloves while collecting the sample. Sample containers shall be labeled before or immediately after sampling with self-adhesive tags having the following information written in waterproof ink:

- Well I.D.
- Sample I.D. number
- Date and time sample was collected
- Initials of sample collector

4.5.3 Handling, Storage and Transportation of Samples

Upon collection and labeling, all samples shall be placed immediately into a clean chest/cooler with ice to keep samples cool. Exposure to dust, direct sunlight, high temperature, adverse weather conditions, and possible contamination shall be avoided.

All samples will be transported to a State-certified analytical laboratory within 24 hours of collection. Samples shall be transported under chain-of-custody procedures, which document the transfer of custody of samples from the field to the laboratory. Each sample sent to the laboratory for analysis shall be recorded on a Chain-of-Custody Record, which includes instructions to the laboratory for analytical services.

Information contained on the triplicate Chain-of-Custody Record shall include:

- Well No.
- Signature of sampler(s)
- Date and time sampled
- Number of sample containers
- Sample matrix (water)
- Analyses required
- Remarks, including preservatives, special conditions, or specific quality control measures
- Turnaround time and person to receive laboratory report
- Method of shipment to the laboratory
- Release signature of sampler(s), and signatures of all people assuming custody
- Condition of samples when received by laboratory

Blank spaces on the Chain-of-Custody Record will be crossed out between the last sample listed and the signatures at the bottom of the sheet.

The field sampler shall sign the Chain-of-Custody Record and record the time and date at the time of transfer to the laboratory or to an intermediate person. A set of signatures is required for each relinquished/reserved transfer, including intermediate transfers. The original imprint of the Chain-of-Custody Record will accompany the sample containers. A duplicate copy shall be placed in the project file.

If the samples are to be shipped to the laboratory, the original Chain-of-Custody will be sealed inside a plastic bag within the ice chest, and the chest shall be sealed with custody tape which has been signed and dated by the last person listed on the Chain-of-Custody. U. S. Department of Transportation shipping requirements shall be followed and the sample shipping receipt retained in the project file as part of the permanent chain-of-custody document. The shipping company

(e.g. Federal Express, UPS, DHL) will not sign the chain-of-custody forms as a receiver, instead the laboratory shall sign as a receiver when the samples are received.

4.5.4 Quality Control Samples

Quality control samples shall consist of duplicates and blanks. At least one duplicate sample shall be collected during each day of sampling. The duplicate sample shall be collected from the same well as the original and immediately after the original sample. At least one blank sample shall be included with each batch of samples delivered to the laboratory. Blank samples shall consist of laboratory prepared deionized water that is containerized at the laboratory and delivered with the sample containers.

4.5.5 Frequency of Measurement

Groundwater quality samples will be collected from agency wells in the Bear Valley Basin and analyzed according to the schedule shown in Table 4-2. The analysis schedule is specified by the DDW.

4.6 Land Subsidence

Monitoring of changes in land surface elevation related to groundwater withdrawal will be conducted through evaluation of satellite data.

4.6.1 Monitoring Features

Changes in land surface elevation over time can be observed on a regional scale using satellite data. The data is generated using interferometric synthetic aperture radar (InSAR). Monthly InSAR datasets will be published on a quarterly basis by the DWR. Additional information on the DWR's InSAR subsidence data is available at https://data.cnra.ca.gov/dataset/tre-altamira-insar-subsidence.

4.6.2 Monitoring Procedure

InSAR data will be downloaded from https://gis.water.ca.gov/arcgisimg/rest/services/SAR to develop maps showing regional land surface changes.

4.6.3 Frequency of Measurement

InSAR data will be downloaded from the DWR website and analyzed on an annual basis for evaluation and incorporation into the annual reports.

4.7 Depletions of Interconnected Surface Water

The measurable objectives developed for groundwater levels in the vicinity of Big Bear Lake and Shay Pond have not resulted in significant and unreasonable surface water conditions in the past. Although a lowering of groundwater levels to the minimum thresholds is not anticipated, ongoing monitoring of the impact of groundwater on surface water and vice versa will be conducted into the future to determine if groundwater levels approaching the minimum thresholds in these areas has an adverse impact on the beneficial uses of the surface water bodies.

4.7.1 Monitoring Features

Monitoring wells used to measure groundwater levels in areas where there is potential for direct groundwater and surface water interaction will be the primary monitoring features from which data is obtained to assess groundwater and surface water interaction. Surface water levels for Big Bear Lake will be obtained from the Big Bear Municipal Water District. Surface water level conditions in Shay Pond will be obtained from the BBCCSD.

4.7.2 Monitoring Procedure

Groundwater levels will be monitored using the procedures described in Section 4.2.1.

4.7.3 Frequency of Measurement

Groundwater level measurement frequency for depletions of interconnected surface water will be monthly, as described in Section 4.2.2.

Surface water stage level data will be compiled annually.

4.8 Representative Monitoring

4.8.1 Groundwater Levels

A subset of groundwater level monitoring features in the monitoring network have been identified as representative monitoring sites to be relied on for the purpose of assessing progress with respect to groundwater level sustainability in the Bear Valley Basin. The representative groundwater level monitoring sites are shown on Figure 2-31. At least one representative groundwater level monitoring site has been identified within each management area.

4.8.2 Reduction of Groundwater Storage

Changes in groundwater storage within the Bear Valley Basin will be estimated using the method described in Section 4.3 of this GSP. Groundwater level data to be relied on for the change in groundwater storage estimates will be collected as described in Section 4.2 of this GSP from the monitoring network shown on Figure 2-31 and summarized in Table 2-7. As such, there are no single representative monitoring sites for evaluating progress with respect to groundwater sustainability as it relates to changes in groundwater storage in the Bear Valley Basin.

4.8.3 Seawater Intrusion

Seawater intrusion cannot occur in the Bear Valley Basin due to its location with respect to the Pacific Ocean (see Section 3.4.3 herein). As such, representative monitoring sites for evaluating progress with respect to groundwater sustainability as it relates to seawater intrusion are not needed.

4.8.4 Degraded Groundwater Quality

Groundwater quality degradation in the Bear Valley Basin is being monitored and regulated in accordance with California DDW drinking water requirements. Groundwater produced from any municipal well in the basin that does not meet regulatory requirements for potable supply is considered an undesirable result. As such, all municipal production wells in the Bear Valley Basin serve as representative monitoring sites for groundwater quality.

4.8.5 Land Subsidence

Changes in land surface elevation across the Bear Valley Basin will be monitored using satellite data as described in Section 4.6 of this GSP. As such, there are no single representative monitoring sites for evaluating changes with respect to land subsidence in the Bear Valley Basin.

4.8.6 Interconnected Surface Water

The groundwater level data collected from the groundwater level monitoring network will serve as a proxy for monitoring changes with respect to interconnected surface water in the Bear Valley Basin. As such, the representative monitoring sites identified for evaluating groundwater sustainability as it relates to groundwater levels will also serve as the representative monitoring sites for evaluating interconnected surface water.

4.9 Data Management System

As per SGMA Regulations § 352.6, a data management system (DMS) has been developed for data filing, storage, and security during the implementation of the Bear Valley Basin GSP. Certain types of data necessary to implement the GSP and prepare annual reports will be stored in a relational computer database (Microsoft Access) that will enable the efficient communication and display of data, when needed. The general types of data to be stored in the database will include:

- Information on wells, including name, location, and construction
- Groundwater production
- Groundwater levels

Other types of data may be added to the database, as deemed necessary by the BVBGSA.

The database will be maintained by the BVBGSA or its technical representative. Data will be compiled and stored in the database, at a minimum, annually. The updated database will be made available to the BVBGSA managers and/or their technical representative(s) by December 1 of each year to provide the information necessary to prepare annual reports.

The BVBGSA and/or their technical representative will implement measures to prevent accidental loss of data and tampering with the database. All data entered in the database will be saved during each work session. The database will be backed up on a separate external drive or offsite (i.e. "cloud") server following each session. Access to the working database files will be limited to the BVBGSA managers, staff, and their assigned technical representatives.

For purposes of this plan, quality assurance (QA) is defined as the integrated program designed to assure reliability of monitoring and measurement data. Quality control (QC) is defined as the routine application of specified procedures to obtain prescribed standards of performance in the monitoring and measurement process (ASTM D-18). BBDWP and their assigned technical experts are responsible for assuring that the precision, accuracy, and completeness of data collected during as part of this GSP are known and documented. Accordingly, all field instruments will be operated in strict accordance with manufacturers specifications. All data and data collection procedures will be checked by a California Certified Hydrogeologist.

Explanation of Units
NTU - nephelometric turbidity units
mg/L - milligrams per liter
µmhos/cm - micromhos per centimeter
µg/L - micrograms per liter
pCi/L - picocuries per liter
ng/L - nanograms per liter

*Temperature, pH, electrical conductivity and turbidity will also be measured in the field.

5. Project and Management Actions

This chapter describes the Projects, Management Actions, and Adaptive Management information that satisfies Sections 354.42 and 354.44 of the Sustainable Groundwater Management Act (SGMA) regulations. These projects, actions, and their benefits are intended to help achieve the sustainable management goals in the Basin.

Groundwater pumping within the Bear Valley Basin, as a whole, has historically been within the Sustainable Yield resulting in relatively stable long-term groundwater levels. While there have periodically been localized groundwater level declines, pumping sustainability has been maintained through adaptive management of pumping distribution between management areas and implementation of conservation measures. To maintain pumping sustainability into the future, the BVBGSA plans to continue these effective management actions on a routine basis and implement projects as needed that support sustainable management. These projects and management actions are described in detail in the following sections.

5.1 Introduction

Per Section 354.44 of the SGMA regulations, the GSP is to include the following:

a) Each Plan shall include a description of the projects and management actions the Agency has determined will achieve the sustainability goal for the basin, including projects and management actions to respond to changing conditions in the basin.

b) Each Plan shall include a description of the projects and management actions that include the following:

1. *A list of projects and management actions proposed in the Plan with a description of the measurable objective that is expected to benefit from the project or management action. The list shall include projects and management actions that may be utilized to meet interim milestones, the exceedance of minimum thresholds, or where undesirable results have occurred or are imminent. The Plan shall include the following:*
    - A. *A description of the circumstances under which projects or management actions shall be implemented, the criteria that would trigger implementation and termination of projects or management actions, and the process by which the Agency shall determine that conditions requiring the implementation of particular projects or management actions have occurred.*
    - B. *The process by which the Agency shall provide notice to the public and other agencies that the implementation of projects or management actions*

is being considered or has been implemented, including a description of the actions to be taken.

2. *If overdraft conditions are identified through the analysis required by Section 354.18, the Plan shall describe projects or management actions, including a quantification of demand reduction or other methods, for the mitigation of overdraft.*
3. *A summary of the permitting and regulatory process required for each project and management action.*
4. *The status of each project and management action, including a timetable for expected initiation and completion, and the accrual of expected benefits.*
5. *An explanation of the benefits that are expected to be realized from the project or management action, and how those benefits will be evaluated.*
6. *An explanation of how the project or management action will be accomplished. If the projects or management actions rely on water from outside the jurisdiction of the Agency, an explanation of the source and reliability of that water shall be included.*
7. *A description of the legal authority required for each project and management action, and the basis for that authority within the Agency.*
8. *A description of the estimated cost for each project and management action and a description of how the Agency plans to meet those costs.*
9. *A description of the management of groundwater extractions and recharge to ensure that chronic lowering of groundwater levels or depletion of supply during periods of drought is offset by increases in groundwater levels or storage during other periods.*

c) *Projects and management actions shall be supported by best available information and best available science.*

d) *An Agency shall take into account the level of uncertainty associated with the basin setting when developing projects or management actions.*

5.2 Projects

Based on discussion with the BVBGSA stakeholders, two projects or types of projects have been identified for inclusion in the GSP because they support efforts to maintain long term groundwater sustainability:

- Replenish Big Bear
- Any projects that provide new or maintain existing groundwater pumping facilities

These projects are described in detail in the following sections.

5.2.1 Replenish Big Bear Project

Replenish Big Bear is a multi-benefit recycled water project that will utilize a water resource currently discharged outside of the Bear Valley Basin to secure a new drought proof local water supply that will support continued groundwater sustainability, among other benefits.

Replenish Big Bear includes permitting, design, and construction of treatment facility upgrades at the existing BBARWA Wastewater Treatment Plant (WWTP) to produce high quality recycled water, approximately 7 miles of pipeline for recycled water conveyance, three pump stations, a groundwater recharge facility, monitoring wells, and brine minimization and disposal facilities.

The project will produce approximately 1,950 acre-feet per year (AFY) of high-quality recycled water for various uses. Approximately 1,900 AFY will be discharged to Stanfield Marsh, which subsequently flows into Big Bear Lake (Lake). Pending confirmation of its suitability for use to sustain habitat for the endangered unarmored threespine stickleback fish, approximately 50 AFY of the treated water may be discharged on a continuous basis to Shay Pond in the Erwin Lake area, which is currently sustained with groundwater pumped from BBCCSD wells.

Of the water discharged to the Lake, some of it can be extracted and conveyed to Sand Canyon for groundwater recharge. The recharge potential at Sand Canyon is approximately 380 AF over a 6-month dry weather period (April – October) (TH&Co, 2017b). Groundwater recharge at Sand Canyon may require construction of monitoring wells to monitor water quality in the area, subject to regulatory permit conditions.

Water can also be extracted from the Lake to irrigate Bear Mountain Golf Course, which currently uses approximately 120 AFY from private groundwater wells for irrigation. The additional surface water available as a result of Replenish Big Bear would provide irrigation water in lieu of groundwater pumping, thus reducing the demand on the aquifer system in an area where groundwater levels have been declining.

While some of the 1,900 AFY of recycled water discharged to the Lake will later be extracted and used to supplement groundwater supplies, most of that water will remain in the Lake to help stabilize Lake levels and provide recreational and habitat benefits. As summarized in Table 5-1, up to 550 AFY of the water produced will benefit groundwater in the Bear Valley Basin.

An overview map of the project is shown on Figure 5-1.

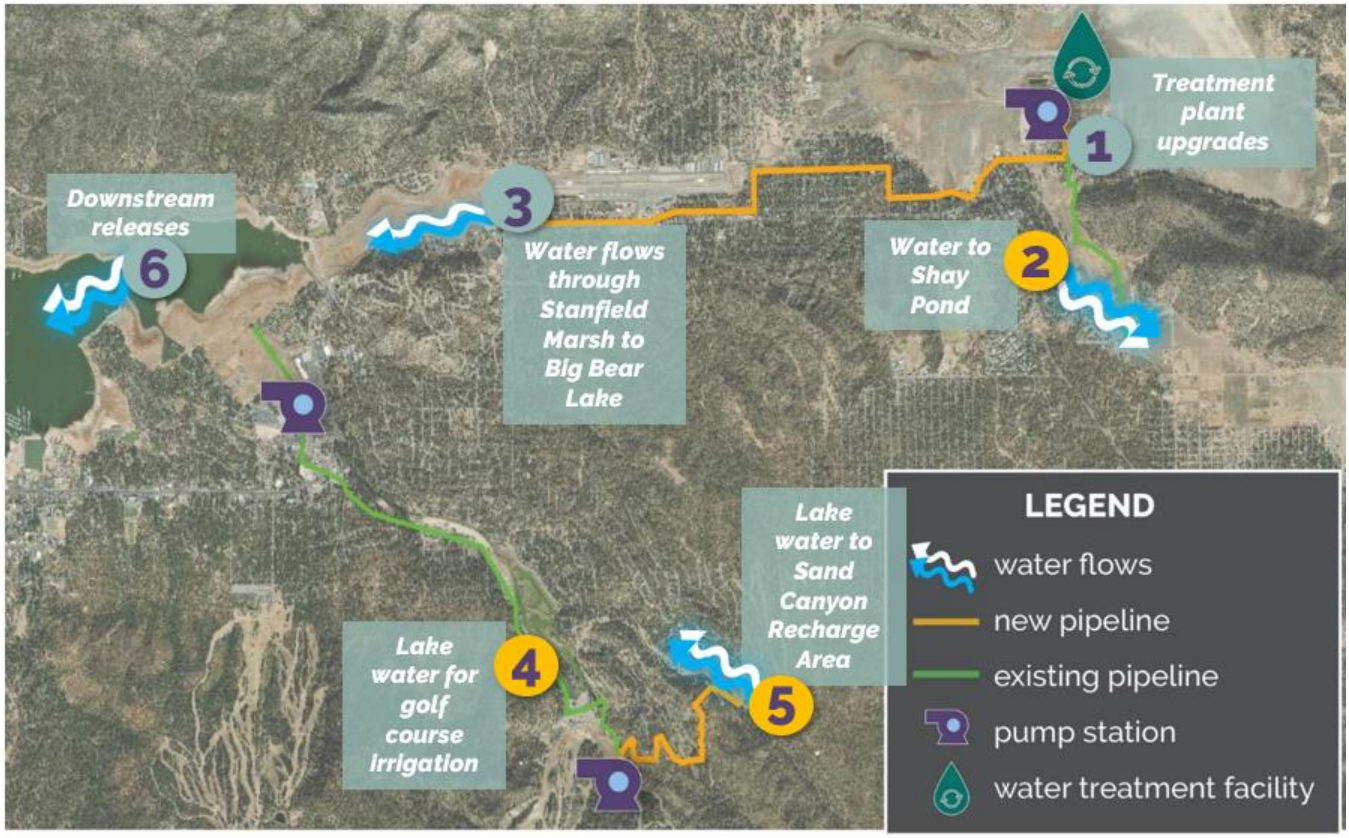

Figure 5-1. Replenish Big Bear Project Overview

5.2.1.1 Planned Treatment Plant Upgrades

Upgrades will be necessary to BBARWA's existing WWTP to meet the water quality objectives (WQOs) identified for the Lake in the Santa Ana Basin Plan (Basin Plan), the total phosphorus target identified in the Big Bear Lake Nutrient Total Maximum Daily Load for the Dry Hydrologic Conditions (TMDL) and regulatory requirements for groundwater recharge. To meet the WQOs and TMDL targets for the Lake, total dissolved solids (TDS), inorganic nitrogen and phosphorus concentrations must be reduced through multiple in-series treatment processes to meet the anticipated discharge limits – 175 mg/l, 0.15 mg/L and 0.035 mg/L, respectively. To achieve these expected strict effluent limits, BBARWA is planning to implement a series of advanced treatment upgrades to existing unit processes and integrate new unit processes, specifically:

- Upgrade the extended aeration process through retrofit of the existing oxidation ditches to optimize biological nitrification-denitrification (NDN).
- Nutrient-laden liquid sidestreams, which are produced during solids handling processes, may require treatment to mitigate reduced treatment capacity impacts from returning high nutrient loads to liquid stream processes.

- Addition of a denitrification filter to reduce nitrate-nitrogen concentrations and provide chemical phosphorus removal.
- Low-pressure filtration, such as ultrafiltration (UF), to reduce flocculated or colloidal solids upstream of the reverse osmosis (RO) process.
- RO to reduce TDS and nutrient concentrations.
- Pellet reactor brine minimization system to minimize brine stream from RO process.
- Addition of ultraviolet (UV) disinfection to deactivate any bacteria, viruses, and other microorganisms.

It is anticipated that 100% of the water discharged to the Lake and Shay Pond will be treated with RO and UV disinfection to meet the strict WQO. The permitting process with the Regional Water Quality Control Board (RWQCB) and DDW is ongoing, so the specifics of the treatment processes have yet to be finalized. Additional coordination with the California Department of Fish and Wildlife (CDFW) and United States Fish and Wildlife Serve (USFWS) is anticipated to occur once the Lake discharge requirements are better defined. However, the final treatment process intends to comply with all regulatory permitting requirements for discharge to the Lake and Shay Pond.

Incorporation of RO into the treatment process will require a brine management system. The preliminary RO brine management option for Replenish Big Bear is a brine minimization pellet reactor to minimize brine from the RO brine stream, followed by solar evaporation ponds located at a site near BBARWA. Using an RO recovery of 90% for the treated flow and RO influent of 2.2 million gallons per day (MGD) would result in 0.22 MGD of RO brine to be minimized through the pellet reactor, and approximately 0.022 MGD of brine to be conveyed to the evaporation pond. A total evaporation pond area of 23 acres is needed for the RO brine flows, which will be conveyed to evaporation ponds in Big Bear adjacent to the BBARWA WWTP. Alternative RO brine management strategies will be evaluated further as the Project enters the design phase.

5.2.1.2 Advanced Treated Water Quality

The water produced by the BBARWA WWTP, after the upgrades described in Section 5.2.1.1 are implemented, will be of high quality and is anticipated to satisfy WQOs and permitting requirements for discharge into the Lake and Shay Pond.

As part of the discharge permit for the project, it will be necessary to conduct a pilot test of the treatment process to demonstrate that the final treated water complies with regulatory requirements. As part of the project development process, a study of the treated product water will be conducted to confirm that the physical and chemical characteristics of the advanced treated product water are suitable for sustaining the unarmored threespine stickleback fish habitat in Shay Pond. Coordination with the CDFW and USFWS is anticipated to prepare the scope of work for

the fish survivability study and to interpret the results. The BBARWA will not discharge treated Project water to Shay Pond until it is determined that the quality of the water will not adversely impact the fish habitat.

5.2.1.3 Project Benefits

The various components of Replenish Big Bear provide multiple benefits to the Valley, including enhanced groundwater sustainability, increased Lake levels, and associated recreation, ecosystem and economic benefits. This section focuses on the groundwater benefits that support the sustainable management goals of the GSP. More information on the full components and benefits of Replenish Big Bear can be found on the project website at ReplenishBigBear.com.

The groundwater benefits associated with each project component and the Sustainable Management Criteria addressed are detailed in Table 5-1.

Table 5-1. Replenish Big Bear Groundwater Benefits

Component	Estimated Supply	Groundwater Benefit	Sustainable Management Criteria Addressed
WWTP Upgrades	Included below	Produces a new, high-quality drought proof source of supply that provides numerous benefits to the Valley, including supporting groundwater sustainability.	CHRONIC LOWERING OF GROUNDWATER LEVELS REDUCTION OF GROUNDWATER STORAGE
Shay Pond Discharge	50 AFY	Provides a new source of water for potential discharge to Shay Pond to sustain endangered species habitat. Groundwater from BBCCSD wells currently used for this purpose can be stored in the basin instead, helping to sustain groundwater levels and storage. Helps maintain the Measurable Objective of groundwater level for the Erwin Management Area.	
Sand Canyon Groundwater Recharge	380 AFY	Provides a new source of water to supplement natural recharge in Sand Canyon, which will increase groundwater levels and storage. Increases adaptive management opportunities by providing additional water that can be pumped out by BBLDWP and transferred to BBBCCSD using exisitng interconnections. Helps achieve the Measurable Objective of groundwater level for various Management Areas. Effectively increases Sustainable Yield by approximately 380 AFY.	
Bear Mountain Golf Resort Irrigation	120 AFY	Provides a new source of water for irrigation of the golf course. Groundwater from private wells currently used for this purpose can be stored in the basin instead, helping to sustain groundwater levels and storage. Helps achieve the Measurable Objective of groundwater level for various Management Areas.	

5.2.1.4 Supply Reliability

As previously mentioned, groundwater is the only potable water supply in the Bear Valley Basin. Efforts by the water agencies and community have been successful in reducing demand; and total potable consumption has been maintained below the Sustainable Yield of the groundwater basin. BBLDWP and BBCCSD have implemented a series of ongoing conservation, education and outreach programs to help reduce water usage in the service area. In the past decade, BBLDWP and BBCCSD have maintained a decreasing trend in per capita demands through conservation efforts. However, while past conservation efforts have been very effective, the agencies expect that additional demand reduction will become slower and more difficult or costly to achieve in the future. As more and more customers take advantage of water efficient fixture upgrades, low water use landscaping and adopt more efficient water use behaviors, additional opportunities for customers to further reduce water demand will become more limited.

In addition, climate change is anticipated to have an impact on the timing and intensity of precipitation, which will impact how much natural runoff can percolate into the groundwater basin. Climate change models indicate that these changes will result in a reduction of Sustainable Yield in the Bear Valley Basin over time, as discussed in Section 2.3.9 of this GSP.

If Sustainable Yield declines over time, growth in the Valley continues and water users have limited ability for further conservation, additional supply will likely be needed in the future to maintain supply reliability. The drought proof supply provided by Replenish Big Bear will become more critical to maintain water reliability in times of extended drought and provide insurance against climate change uncertainty.

5.2.1.4.1 Groundwater Depletion

The Project would provide substantial benefits to help mitigate localized imbalances in the Bear Valley Basin. While the Bear Valley Basin as a whole is sustainable, there are localized areas that show persistent groundwater level declines, which may exceed established sustainability criteria if allowed to continue. One such area is in the vicinity of the Sand Canyon Golf Course. The greens for the course are irrigated, in part, from private wells located on or near the property. As shown on Figure 5-1, groundwater levels in the monitoring well Sand Canyon No. 1, which were evaluated for the GSP, have shown an overall decline since 1992, despite periodic recovery during wet years. Without a change in groundwater management in the area, groundwater levels in this well could drop below the minimum threshold by 2042 (see Figure 5-1)

The Project will include the future option to pump 380 AF of blended recycled water and Lake water from the Lake to Sand Canyon, thus providing an alternative source of water for the Sand Canyon Golf Course. As the golf course is the primary groundwater pumper in the area, in-lieu

water supply from the Project is anticipated to have the beneficial effect of stabilizing groundwater levels and avoiding undesirable results.

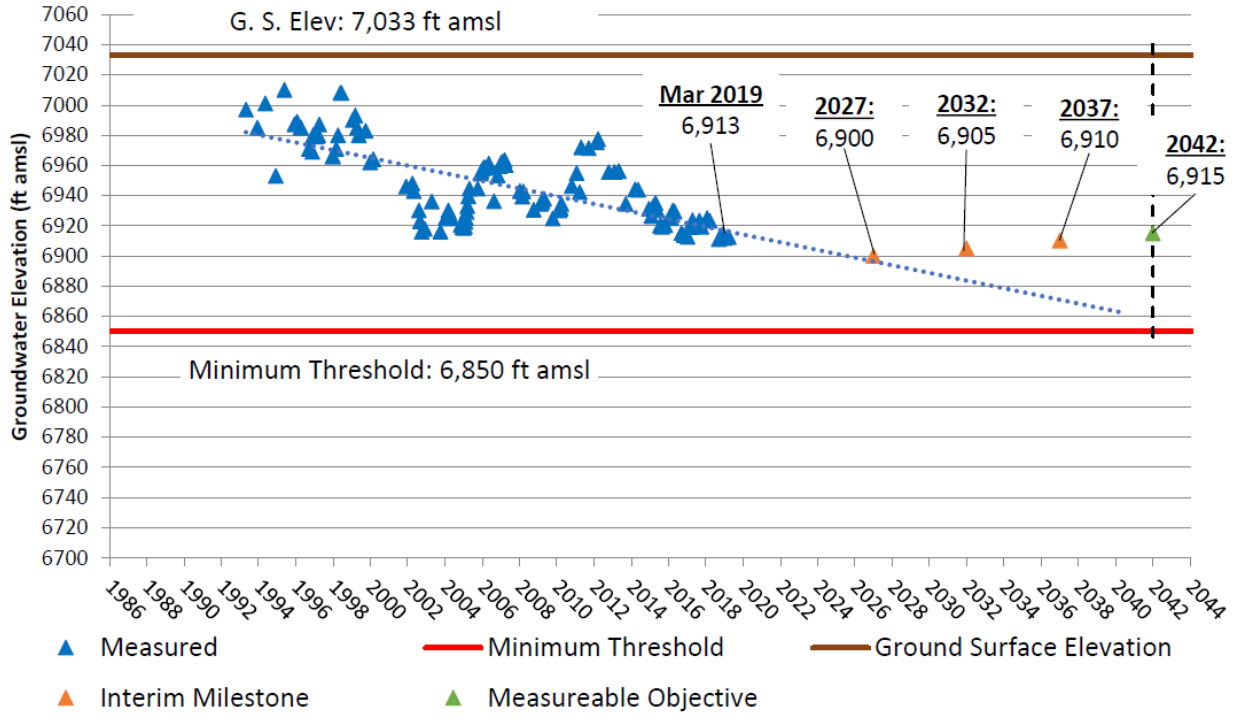

Figure 5-1. Groundwater Elevation Hydrograph, Sand Canyon Well #1

5.2.1.4.2 Availability of Alternative Supplies

The water agencies in the Bear Valley Basin rely solely on groundwater to supply municipal potable water demand. Absent Replenish Big Bear, surface water in Big Bear Lake is not available for municipal water supply in Big Bear as the lake is adjudicated and the natural inflows are reserved for other uses. Imported water, such as from the State Water Project (SWP), is not financially feasible due to the lack of infrastructure to the Valley's high elevation and isolated location. Also, there is a concern that the reliability of SWP imported supplies will continue to decrease due to multiple factors including increased demands for environmental uses and municipal demand increases with growing populations. Replenish Big Bear will provide a local, drought-resistant water supply with up to 550 AFY used to sustain groundwater levels and storage in the Basin.

5.2.1.5 Project Costs

The estimated Replenish Big Bear capital cost is approximately $55,717,000 with an annual O&M of $2,438,000. This includes the cost of the treatment upgrades at the BBARWA WWTP, as described in Section 5.2.1.1 herein, to produce the high-quality recycled water and the cost of pipelines and pump stations to convey the water to the various use locations.

To date, Replenish Big Bear has been awarded approximately $6.7 million in grant funding toward capital costs. The project team is continuously identifying and applying for new funding sources and anticipates receiving additional grant funding. Project costs not paid for by grant funding will likely be paid for through a combination of local funding sources and funding from project partners associated with the project benefits provided. The project team is currently in the process of identifying funding sources.

5.2.1.6 Project Implementation

The BVBGSA will continue to monitor projected Sustainable Yield and projected pumping to estimate when additional supply may be needed. However, due to the extended drought in recent years and the availability of grant funding to support drought resilience projects, the BVBGSA members are working to implement Replenish Big Bear in the near term to proactively address the threat of drought and begin accumulating local storage to reduce the impact of future droughts on groundwater sustainability.

The Replenish Big Bear Team, which consists of all of the member agencies of the BVBGSA, is working to obtain the necessary permitting to continue the project implementations. The current schedule anticipates completing the project by November 2025. However, the regulatory process is on the critical path and may cause the project schedule to be extended for reasons outside the agencies' control.

Once it is demonstrated that the treated Project water will be suitable for use in Shay Pond, the Replenish Big Bear Team will work with the CDFW and USFWS to develop a monitoring plan to monitor any adverse effects on the fish from changing the source of water to the pond. The existing well currently providing water to the pond will be kept on standby to provide a backup source of water should adverse impacts be observed.

5.2.1.7 Basin Uncertainty (§ 354.44.9d)

While Replenish Big Bear will help mitigate localized groundwater level and storage imbalances in the near-term, its greatest benefit will be providing insurance against uncertainty in future long-term climate change projections that affect groundwater supply in the Bear Valley Basin. Based on the current climate change projections provided by the CDWR, the average Sustainable Yield

of the basin is projected to decrease from approximately 5,300 acre-ft/yr in 2020 to approximately 4,300 acre-ft/yr by 2070 (see Figure 2-30). If current groundwater pumping projections are accurate, it is possible that pumping can be maintained below the climate-adjusted Sustainable Yield in the 50-year SGMA planning horizon. However, there is uncertainty in both the climate change projections and the pumping projections. If climate change has a bigger impact on water supply than projected, it is possible that pumping could exceed the long-term average Sustainable Yield within the 50-year SGMA planning horizon, which would result in long-term overdraft. Pumping demand in excess of that projected could also result in pumping exceeding Sustainable Yield. This uncertainty is directly addressed by the aspects of Replenish Big Bear that result in groundwater recharge and reduced groundwater pumping demand, both of which work to stabilize groundwater levels, increase groundwater in storage, and increase the Sustainable Yield of the Bear Valley Basin.

5.2.1.8 Legal Authority

California Water Code (CWC) §10726.2 provides GSAs the authority to purchase, among other things, land, water rights, and privileges. The BBARWA has the legal authority to sell the recycled water to BBCCSD and BBLDWP to recharge the Basin.

5.2.1.9 Permitting and Regulatory Processes

BBARWA will be responsible for acquiring permits needed for the discharge of recycled water to Shay Pond and Stanfield Marsh/Big Bear Lake. Permits for extraction of water from the Lake and discharge to the golf course and Sand Canyon are expected to be issued separately and may be issued to BBLDWP, BBCCSD and/or BBMWD.

Permits have not yet been acquired, but the Replenish Big Bear Team has initiated communications with the Regional Water Quality Control Board (RWQCB), United States Environmental Protection Agency (EPA), and the State Water Resources Control Board Division of Drinking Water (DDW) to discuss the permitting approach for the proposed discharge points. Permits will be pursued as early as possible during the design process. Coordination is underway with the permitting agencies to determine the Project's permitting strategy and the required technical studies. Anticipated new or modified permits/approvals include but are not limited to the following:

Federal Agencies:

- EPA – Total Maximum Daily Load (TMDL) compliance for discharge to Stanfield Marsh / Big Bear Lake

- USBR – National Environmental Policy Act (NEPA) lead agency which may require coordination with other federal agencies such as United States Fish and Wildlife Service, State Historic Preservation Office, Army Corps of Engineers, and National Marine Fisheries Service.

State Agencies:

- RWQCB – National Pollutant Discharge Elimination System (NPDES) for discharge to Stanfield Marsh / Big Bear Lake
- RWQCB – NPDES or Waste Discharge Requirement (WDR) for discharge to Shay Pond
- RWQCB – General Construction Permit
- RWQCB –WDR modification for changes in operation and the addition of RO brine evaporation in Big Bear.
- RWQCB – WDR for discharge to Sand Canyon
- SWRCB – Recycled Water Use Statewide General Permit
- DDW – Permitting requirements to be determined following ongoing coordination
- Caltrans – Encroachment permits for pipelines within the Caltrans Right-of-Way
- California Department of Fish and Wildlife – Approval for discharge to Shay Pond including a Lake and Streambed Alteration permit

Local Agencies:

- The City of Big Bear Lake and/or San Bernardino County – Encroachment permits for improvements within the respective Rights-of-Way
- The City of Big Bear Lake and/or San Bernardino County – Grading and building permits for treatment upgrades and the recharge basin
- South Coast Air Quality Management District – Authority to Construct and Permit to Operate the WWTP upgrades
- The Big Bear Watermaster

The Replenish Big Bear Team will work with the RWQCB, DDW, CDFW and USFWS to obtain the appropriate discharge permit(s) for Shay Pond and the Lake.

In accordance with CEQA, the Replenish Big Bear Team will prepare an Environmental Impact Report (EIR). Since federal funding is being pursued through Reclamation's Title XVI Program, an Environmental Impact Statement (EIS) or Environmental Assessment (EA) will also be prepared to comply with NEPA. All environmental documentation will require Replenish Big Bear to comply with endangered species laws, including the California Endangered Species Act and the Federal Endangered Species Act.

The Replenish Big Bear Team intends to proactively monitor and manage permitting needs and timelines to implement construction and operation of Replenish Big Bear in an efficient and timely manner.

5.2.1.10 Public Notice and Outreach

Information about Replenish Big Bear, project status updates and public meetings are shared with the public on the project website, ReplenishBigBear.com, as well as on social media, and in press releases and newspaper articles. In addition, members of the project team routinely present project updates at community meetings and public meetings, including BVBGSA meetings and the meetings of the BVBGSA members.

5.2.2 Groundwater Pumping Facilities

One of the primary strategies Bear Valley Basin agencies have used to maintain Basin-wide groundwater sustainability is adaptive management of groundwater pumping among the various Management Areas. This strategy works by shifting groundwater pumping from localized areas with declining groundwater levels to other areas with more stable groundwater levels. Basin groundwater levels and conditions change over time and may vary by Management Area so operational flexibility in the BBLDWP and BBCCSD water systems is necessary to support this adaptive management strategy. This flexibility is achieved by maintaining groundwater pumping facilities distributed throughout the Basin and by maintaining more pumping capacity than the minimum required to meet demands, particularly peak demands. This allows the agencies to turn off some wells for a period of time if groundwater levels indicate the need to reduce pumping, while still being able to provide reliable water service to the community.

There are a few Management Areas of the Bear Valley Basin that are underutilized with respect to groundwater resources. These include East Baldwin, Lake Williams, and Mill Creek. In East Baldwin, aside from private well pumping, there is no municipal pumping currently in the Management Area. The BBCCSD is currently drilling and constructing a new well in this Management Area to take advantage of the groundwater resources and increase operational flexibility. No new wells are currently planned for the Lake Williams and Mill Creek Management Areas. In Lake Williams, the existing wells are adequate to meet demand and in Mill Creek, naturally occurring groundwater quality issues (i.e. arsenic and uranium) prevent the groundwater in that area from being utilized for municipal supply. The groundwater resources in both of these Management Areas are underutilized. Future wells could be drilled in both Management Areas to provide additional operational flexibility for the agencies as well as address expected growth projections.

In addition to developing underutilized groundwater resources in the basin, maintenance of existing groundwater production facilities is essential to maintain operational flexibility to meet water demands. Currently, the BBLDWP and BBCCSD have more than 60 active wells in the Bear Valley Basin. Many of these wells and their associated pumping plants are nearing the end of their useful life of approximately 50 to 60 years and need to be repaired or replaced. In some cases, well replacement can be coordinated with the development of groundwater resources in underutilized Management Areas. Such projects are typically identified in an agency's Water Master Plan and consider expected growth projections.

In summary, there are numerous types of projects related to groundwater pumping facilities that may be needed to support the adaptive management strategy:

- Routine inspection and maintenance of wells
- Abandonment of wells that have reached the end of their life
- Drilling of new wells to replace abandoned wells
- Drilling of new wells to meet future growth
- Routine inspection, maintenance and replacement of well pumping equipment

These types of are projects routinely undertaken by BBLDWP and BBCCSD as part of their water system maintenance and will vary over time, so specific projects are not detailed in this GSP. Rather, the types of projects are described in this GSP to underscore the importance of these activities to maintaining long term Basin-wide groundwater sustainability.

The groundwater benefits associated with these projects and the Sustainable Management Criteria addressed are detailed in Table 5-1.

Table 5-2. Groundwater Pumping Facility Project Groundwater Benefits

Project	Groundwater Benefit	Sustainable Management Criteria Addressed
Well Maintenance and Replacement Pumping Equipment Maintenance and Replacement Drilling New Wells	Maintenance and expansion of groundwater pumping capacity in various locations throughout the Basin is critical to maintaining the operational flexibility needed to support adaptive management of groundwater pumping. Adaptive management may enable agencies to shift pumping away from localized areas of groundwater decline to limit decline to an acceptable level and recover through recharge.	CHRONIC LOWERING OF GROUNDWATER LEVELS REDUCTION OF GROUNDWATER STORAGE

5.2.2.1 Project Costs

The cost of groundwater pumping facility projects varies depending on the scope of necessary repairs or replacements. These costs are typically planned for in the annual operating and capital budgets adopted by BBLDWP and BBCCSD for their respective water systems and are funded by revenue from water sales, connection fees and grants, as appropriate.

5.2.2.2 Project Implementation

BBLDWP and BBCCSD will continue to be responsible for identifying and implementing projects as needed to maintain or expand their respective groundwater pumping facilities. Projects are typically identified and annual budgets and periodic Water Master Plan documents or other studies.

5.2.2.3 Basin Uncertainty

Maintaining operational flexibility will help the agencies respond to changes in actual Basin conditions based on routine monitoring, which mitigates uncertainty in the Basin setting information.

5.2.2.4 Legal Authority

BBLDWP and BBCCSD own their respective groundwater pumping facilities and have the legal authority to maintain or replace them as needed.

5.2.2.5 Permitting and Regulatory Processes

BBLDWP and BBCCSD will continue to be responsible for acquiring any permits needed for the drilling of new or replacement groundwater wells. Routine maintenance activities typically do not require permits. Discharges related to well maintenance are conducted under each agencies National Pollutant Discharge Elimination System (NPDES) permit.

Anticipated permits/approvals for new or replacement wells may include but are not limited to the following:

- San Bernardino County Department of Public Health Well Permit
- RWQCB –Construction Stormwater General Permit
- DDW – Modification of Drinking Water System Permit to include the new facility
- Caltrans – Encroachment permits for improvements or construction activities within the Caltrans Right-of-Way
- The City of Big Bear Lake and/or San Bernardino County – Encroachment permits for improvements within the respective Rights-of-Way
- South Coast Air Quality Management District – Authority to Construct and Permit to Operate a new well

In accordance with CEQA, the Replenish Big Bear Team will prepare an Environmental Impact Report (EIR). Since federal funding is being pursued through Reclamation's Title XVI Program, an Environmental Impact Statement (EIS) or Environmental Assessment (EA) will also be prepared to comply with NEPA.

The Replenish Big Bear Team intends to proactively monitor and manage permitting needs and timelines to implement construction and operation of Replenish Big Bear in an efficient and timely manner.

5.2.2.6 Public Notice and Outreach (§ 354.44B)

Information about planned groundwater pumping facility projects is presented at public meetings of the BBLDWP and BBCCSD Boards of Directors and is included in proposed and adopted annual budget materials and planning documents, which are public records available to the public.

5.3 Management Actions

The management actions in this Plan include continuing the existing adaptive management activities and water use efficiency measures the purveyors have implemented for many years.

5.3.1 Technical Review Team

A Technical Review Team (TRT) for the BBLDWP has been meeting routinely since 2004 to review Basin conditions and pumping in their service area and recommend actions needed to maintain Basin-wide sustainability. BBCCSD has historically provided their groundwater level data as input to the TRT process but has not been directly involved. The TRT will be expanded to include direct participation by the BBCCSD and will continue to meet routinely to evaluate data and make basin management decisions in the context of the Sustainable Management Criteria in this GSP. The TRT will meet a minimum of once per year but may increase the frequency to twice or more per year during drought conditions. The TRT will review the groundwater levels at each of the Representative Monitoring Stations and compare them with the Interim Milestones and Measurable Objectives established for each Management Area. The TRT will also review pumping data for the prior year for comparison with the estimated Sustainable Yield of the Basin.

The TRT may provide recommendations for adaptive basin management based on review of basin conditions and pumping. The TRT may recommend shifting pumping from a localized area with declining groundwater levels to areas with more stable groundwater levels. The General Manager of the respective agencies may then authorize a change to their respective operating strategy based on the recommendations of the TRT. The TRT may also recommend declaration of a water supply shortage stage in BBLDWP and BBCCSD's respective Water Shortage Contingency Plans, as discussed further in Section **Error! Reference source not found.**. Any such recommendation w ould be provided to the Board of Directors of the respective agencies for consideration; the TRT has no authority to declare a shortage.

5.3.2 Water Use Efficiency

BBLDWP and BBCCSD have implemented a variety of water use efficiency measures over the course of many years and have been successful in reducing demand; total potable consumption has been maintained below the Sustainable Yield of the groundwater basin. In the past decade, BBLDWP and BBCCSD have maintained a decreasing trend in per capita demands through conservation efforts.

BBLDWP and BBCCSD continue to implement a range of programs to help improve water use efficiency in the Valley. These programs, also known as Demand Management Measures, are summarized in Table 5-3 and described in detail in their respective 2020 Urban Water Management

Plans (UWMPs), which were adopted in June 2021 following a public comment period. These strategies are aimed to reduce water demands and comply with the state efficiency mandates.

Table 5-3. Demand Management Measures

MEASURE	DESCRIPTION
Water waste prevention ordinances	An ordinance that explicitly states the waste of water is to be prohibited. The ordinance may prohibit specific actions that waste water, such as excessive runoff from landscape irrigation, or use of a hose outdoors without a shut off nozzle.
Metering	Metering supply facilities and customer connections helps agencies and customers accurately account for water use and water loss and identify opportunities to improve water use efficiency. Advanced metering infrastructure (AMI) provides agencies and customers with access to more frequent and timely water use data that can be used to quickly identify leaks and evaluate use patterns that may lead to change in water use behaviors.
Conservation pricing	Tiered water rates where the cost per unit of water increases as the total volume of water used increase has been shown to encourage conservation.
Public education and outreach	Public awareness of the importance of water use efficiency and opportunities and incentives to reduce water use is critical to achieving demand reduction. Methods include bill inserts, media advertising, public signs, school programs for children, website and social media postings, community events and others.
Programs to assess and manage distribution system real loss	Water agencies conduct annual water loss audits to estimate the amount of water loss. Methods to reduce water loss include monitoring and fixing detected leaks, replacing old leaking water mains, and proactively detecting leaks using AMI meter data.
Water conservation program coordination and staffing	An established water conservation program and staff resources to support the program are critical for continued success.
Other demand management measures	Other measures include incentive and rebate programs for water-efficient items and indoor and outdoor conservation audits to help customers identify conservation opportunities.

5.3.3 Water Shortage Contingency Plan

The California Water Code requires urban water suppliers, including BBLDWP and BBCCSD, to have Water Shortage Contingency Plans (WSCPs), which are detailed plans for how each agency intends to predict and respond to foreseeable and unforeseeable water shortages. BBLDWP and BBCCSD most recently updated their WSCPs in June 2021 along with the 2020 UWMPs. Detailed information on the respective WSCPs can be found in the 2020 UWMPs, and a summary is provided here.

A water shortage occurs when the water supply is reduced to a level that cannot support typical demand at any given time. Water shortages can be triggered by a hydrologic limitation in supply (i.e., a prolonged period of below normal precipitation and runoff), limitations or failure of supply and treatment infrastructure, or a combination of conditions. Hydrologic or drought limitations tend to develop and abate more slowly, whereas infrastructure failure tends to happen quickly and

relatively unpredictably, such as during an earthquake. A WSCP is used to provide guidance to an agency's Board of Directors (Board), staff, and the public by identifying anticipated shortages and a range of potential response actions to allow for efficient management of any water shortage with predictability and accountability.

The current WSCPs include a new process to conduct an Annual Water Supply and Demand Assessment (AWSDA) each year, assuming that the following year will be dry, and submit the results to DWR beginning in July 2022. The groundwater level monitoring and pumping data evaluated by the TRT will also support each agency's determination of expected supplies and demands for the coming year. If the result of the TRT review and the AWSDA indicate that a water supply shortage is likely based on either on a shortage of supplies to meet demands or an unacceptable reduction in groundwater levels, the General Manager of the agency may recommend that the Board declare a water shortage at a level needed to address the supply shortage. BBLDWP's WSCP includes seven shortage levels and BBCCSD's includes six shortage levels, ranging from 0% water shortage to a greater than 50% water shortage. Each shortage level has a corresponding set of potential shortage actions that may be implemented as appropriate, with more severe actions corresponding to higher levels of water shortage. The specific shortage response actions vary by agency and can be found in the adopted BBLDWP and BBCCSD WSCPs. Examples of potential shortage response actions that may be implemented at various stages are:

- Limiting landscape irrigation to specific days and times
- Increased public outreach and education to increase awareness of current water supply conditions and the need to conserve water
- Using an intertie between BBLDWP and BBCCSD to transfer water supplies from one to another

The WSCPs are a tool that can be used in coordination with other projects and water management actions as part of GSP implementation to help prevent or address a supply shortage and promote long term groundwater sustainability.

6. Implementation Plan

This chapter is intended to serve as a conceptual roadmap for the BVBGSA to start implementing the GSP over the first five years and discusses implementation effects in accordance with the SGMA regulations sections 354.8(f)(2) and (3).

The implementation plan provided in this chapter is based on current understanding of Bear Valley Basin conditions and includes consideration of the projects and management actions included in Chapter 5, as well as other actions that are needed to successfully implement the GSP including the following:

- GSP implementation, administration, and management
- Funding
- Reporting, including annual reports and 5-year evaluations and updates

6.1 GSP Implementation, Administration, and Management

6.1.1 Administrative Approach/Governance Structure

The BVBGSA will continue to operate under the existing JPA that formed the GSA, unless and until actions are taken amending/revising the existing JPA.

6.1.2 Implementation Schedule

A general summary showing the major activities and estimated timeline for the GSP implementation is provided in Table 6-1. Additional details about the activities included in the schedule are provided in these activities' respective sections of this GSP.

6.1.3 Implementation Costs

Development of this GSP was funded through a Proposition 1 Sustainable Groundwater Planning Grant from DWR, along with in-kind contributions from the BVBGSA members.

The GSA may play a role in pursuing grants and low-interest financing to help pay for GSP implementation costs to the extent possible to offset costs for the GSA members. However, external funding/financing may only be eligible for projects and management action implementation and not ongoing GSP administrative expenses. Ongoing implementation of the GSP is expected to include contributions from the GSA member agencies, which are ultimately funded through customer fees or other public funds.

Costs related to the various activities anticipated for the first five years are shown in Table 6-1. The costs shown are limited to costs of support from consultants and do not include the costs of staff time contributed by BVBGSA member agencies.

Implementation of this GSP is estimated to cost an average of approximately $47,000 per year for the first five years of implementation, excluding the planning and development of the specific projects listed in Chapter 5, which are being implemented and funded separately. Estimates of future annual implementation costs (Years 6 through 20) will be developed during future updates of the GSP based on actual costs incurred in the first 5 years and expected changes for future implementation.

6.1.3.1 DWR Coordination for GSP Approval

After the adopted GSP is submitted to DWR, it will be posted to DWR's website for a public comment period of at least 60 days. DWR will also perform an evaluation of the GSP within two years of submittal and issue a written assessment indicating whether the GSP is approved or requires modifications prior to approval. Coordination with DWR may be needed to support the evaluation process and respond to any questions or comments from DWR. It is anticipated that DWR coordination will be conducted by staff of the of the BVBGSA member agencies with support from consultants as needed.

As shown in Table 6-1, the estimated cost of DWR Coordination for GSP Approval is estimated at approximately $5,000 , but actual costs will depend on the feedback received from DWR.

6.1.3.2 Monitoring Network Implementation

The Monitoring Network will consist of the existing monitoring network used by BBLDWP and BBCCSD to obtain groundwater level and quality data. BBLDWP and BBCCSD routinely collect groundwater level data as part of system operation and monitory water quality in accordance with the State Water Resources Control Board Division of Drinking Water requirements. No additional monitoring requirements are anticipated as part of the GSP. The cost of monitoring is already included in the BBLDWP and BBCCSD annual operating budgets, so no additional costs are included for GSP implementation, as shown in Table 6-1.

6.1.3.3 Technical Review Team

The TRT will meets a minimum of once per year but may increase the frequency to twice or more per year during drought conditions. The TRT will review the groundwater levels at each of the Representative Monitoring Stations and compare them with the Interim Milestones and Measurable Objectives established for each Management Area. The TRT will also review

pumping data for the prior year for comparison with the estimated safe Sustainable Yield of the Basin. Results and recommendations will be documented and included in the GSP Annual Report.

The TRT may provide recommendations for adaptive basin management based on review of basin conditions and pumping. The TRT may also recommend declaration of a water supply shortage stage in BBLDWP and BBCCSD's respective Water Shortage Contingency Plans, as discussed further in Section 5.3.3. The TRT will be led by staff from BBLDWP and BBCCSD with support from a hydrogeologist. In addition, support from a hydrogeologist may be needed between meetings. The annual cost for two (2) TRT meetings and as-needed support throughout a year is estimated to be approximately $9,400.

6.1.3.4 Project Implementation

The costs of specific projects and management actions will like vary year by year, based in part on needed adaptive management activities and the maintenance needs of groundwater pumping facilities.

Groundwater pumping facility maintenance and expansion will continue to be implemented as needed and funded by the owners of the respective facilities through a combination of rates, connection fees and grants.

The Replenish Big Bear project is a joint project with multiple benefits and beneficiaries and funding and financing discussions are underway and have not yet been finalized. The project has already been awarded approximately $6.7 million in grant funding and additional grants funding is being pursued. The GSA may play a role in pursuing additional grants and low-interest financing to help pay for a portion of Replenish Big Bear costs to the extent possible.

6.1.3.5 Reporting

SGMA regulations require the GSAs to submit annual reports to DWR on the status of GSP implementation. SGMA regulations require the GSAs to evaluate the GSP at least every 5 years and whenever the Plan is amended. The reporting requirements for the periodic evaluation are presented in Section 6.2.

It is anticipated that the BVBGSA will obtain the services of a hydrogeology consultant to lead preparation of the annual report, and BVBGSA member agency staff will support by preparing updated hydrographs and summarizing annual groundwater extractions. The estimated cost to prepare an annual report is $22,000/year.

The initial 5-year GSP evaluation is due for submission to DWR in 2027. It is anticipated that the GSA would obtain the services of a hydrogeology consultant to lead preparation of the initial 5-year update. The cost for the initial Five Year GSP update is estimated to be $75,000.

The total cost of reporting over the initial five years of the GSP implementation is estimated to be $185,000.

It is anticipated that the Reporting Costs will be paid for by the GSA member agencies.

6.1.4 Outreach and Communication

To meet the requirements of SGMA, implementation of the GSP will require additional communication and outreach efforts and coordination among the GSA Agencies. The GSA member agency staff will continue to post information and updates on the website and share information and updates at public meetings.

6.2 Reporting

As part of GSP implementation, SGMA Regulation §356.2 requires GSAs to develop annual reports and more detailed five-year evaluations, which could lead to updates of the GSP. The following sections describe the reporting requirements for both the annual reports and five-year evaluations.

6.2.1 Annual Reports

Annual reports will be developed to address current needs in the Basin and the legal requirements of SGMA. As defined by DWR, annual reports must be submitted for DWR review by April 1st of each year following the GSP adoption, except in years when five-year or periodic assessments are submitted. Annual reports are anticipated to include three key sections: General Information, Basin Conditions, and Implementation Progress. The GSA will compile information relevant to annual reports and coordinate collection of information and submit a single annual report for the Basin to DWR.

Development of an annual report will begin following the end of the water year, September 30, and will include an assessment of the previous water year. The annual report will be submitted to DWR before April 1st of the following year. The 2021 annual report covering water year 2021 will be submitted by the GSA by April 1, 2022. Five annual reports for the Basin will be submitted to DWR between 2022 and 2026, prior to the first five-year assessment of this GSP, which is to be submitted to DWR in January 2027.

6.2.1.1 General Information

The General Information section will include an executive summary that highlights the key content of the annual report. This section will include a map of the Basin, a description of the sustainability goals, a description of GSP projects and their progress, as well as an annual update to the GSP implementation schedule.

6.2.1.2 Basin Conditions

Basin conditions will describe the current groundwater conditions and monitoring results in the Basin. This section will include an evaluation of how conditions have changed over the previous year and will compare groundwater data for the water year to historical groundwater data.

Pumping data, effects of project implementation (if applicable), total water use, and groundwater storage data will be included. Key required components include:

- Groundwater level data from the monitoring network, including contour maps of seasonal high and seasonal low water level maps
- Hydrographs of groundwater elevation data at RMS
- Groundwater extraction data by water use sector (including springs and slant wells)
- Groundwater Quality at RMS
- Total water use data
- Change in groundwater in storage
- Subsidence rates and associated survey data

6.2.1.3 Implementation Progress

Progress toward GSP implementation will be included in the annual report. This section of the annual report will describe the progress made toward achieving interim milestones as well as implementation of projects and management actions. Key required components include:

- GSP implementation progress, including proposed changes to the GSP
- Progress toward achieving the Basin sustainability goals

6.2.2 Five-Year Evaluation Reports

As required by SGMA regulations, an evaluation of the GSP and the progress toward meeting the approved sustainable management criteria and the sustainability goal will occur at least every five years and with every amendment to the GSP. A written five-year evaluation report (or periodic evaluation report) will be prepared and submitted to DWR. The information to be included in the evaluation reports is provided in the sections below.

6.2.2.1 Sustainability Evaluation

A Sustainability Evaluation will contain a description of current groundwater conditions for each applicable sustainability indicator and will include a discussion of overall sustainability in the Basin. Progress toward achieving interim milestones and measurable objectives will be included, along with an evaluation of status relative to minimum thresholds.

6.2.2.2 Plan Implementation Progress

A Plan Implementation Progress section will describe the current status of project and management action implementation and whether any adaptive management actions have been implemented since the previous report. An updated project implementation schedule will be included, along with any new projects identified that support the sustainability goals of the GSP and a description of any projects that are no longer included in the GSP. The benefits of projects and management actions that have been implemented will be described and updates on projects and management actions that are underway at the time of the report will be documented.

6.2.2.3 Reconsideration of GSP Elements

As additional monitoring data are collected, land uses and community characteristics change, and GSP projects and management actions are implemented, it may become necessary to reconsider elements of this GSP and revise the GSP as appropriate. GSP elements to be reassessed may include basin setting, management areas, undesirable results, minimum thresholds, and measurable objectives. If appropriate, a revised GSP, completed at the end of the five-year assessment period, will include revisions informed by findings from the monitoring program and changes in the Basin, including changes to groundwater uses, demands, or supplies, and results of project and management action implementation.

6.2.2.4 Monitoring Network Description

A description of the monitoring network will be provided. An assessment of the monitoring network's function will be included, along with an analysis of data collected to date. If data gaps are identified, the GSP will be revised to include a method for addressing these data gaps, along with an implementation schedule for addressing gaps and a description of how the GSA will incorporate updated data into the GSP.

6.2.2.5 New Information

New information available since the last five-year evaluation or GSP amendment will be described and evaluated. If the new information should warrant a change to the GSP, this will also be included, as described previously in Reconsideration of GSP Elements.

6.2.2.6 Regulations or Ordinances

A summary of the regulations or ordinances related to the GSP that have been implemented by DWR or others since the previous report will be provided. The report will include a discussion of any required updates to the GSP.

6.2.2.7 Legal or Enforcement Actions

Legal or enforcement actions taken by the GSA in relation to the GSP will be summarized, including an explanation of how such actions support sustainability in the Basin.

6.2.2.8 Plan Amendments

A description of amendments to the GSP will be provided in the five-year evaluation report, including adopted amendments, recommended amendments for future updates, and amendments that are underway.

6.2.2.9 Coordination

Ongoing coordination will be required among the GSA. The five-year evaluation report will describe coordination activities between these entities such as meetings, joint projects, data collection and sharing, and adaptive management efforts.

6.2.2.10 Reporting to Stakeholders and the Public

Outreach activities associated with the GSP implementation, assessment, and GSP updates will be documented in the five-year evaluation report.

GSP Implementation Activities and Costs (2022-2027)

GSP Implementation Activity	Description	Estimated Cost[2]	Unit	Anticipated Timeframe	Estimated Costs (2022 - 2027)
DWR Coordination for GSP Approval	Coordination with DWR during their evaluation process and response to any questions or comments from DWR	$5,000	Lump Sum	2022 - 2023	$5,000
Monitoring Network Implementation	Complete routine monitoring of groundwater levels and water quality	No additional cost			No additional cost
Technical Review Team	Conduct bi-annual reviews of basin conditions and document results	$9,400	Annual	2022 - 2026	$47,000
Project Implementation[3]	Implementation of Replenish Big Bear and Groundwater Pumping Facility projects	Varies			Budgeted separately
Annual Reports	Compile data and prepare GSP Annual Report	$22,000	Annual	2022 - 2026	$110,000
5-Yr GSP Updates	Compile data and prepare 5-yr GSP Updates,	$75,000	Lump Sum	Q2, 2026 - Q1, 2027	$75,000
				Total Estimated Costs (2022 - 2027)	$237,000
				Average Annual Estimated Cost (2022 - 2027)	$47,000

Notes:

[2]Consultant costs only, does not include staff time contributed by BVBGSA member agencies

[3]The cost for Replenish Big Bear and Groundwater Pumping Facility projects are not included in the Implementation cost estimate. Implementation and funding of these projects will be coordinated and budgeted separately.

Re: Response to Comments Regarding Potential Impacts of the Replenish Big Bear Project on the Lucerne Valley Land Discharge Location

The purpose of this Technical Memorandum (TM) is to provide supporting documentation and analysis to address comments received regarding the Replenish Big Bear Project (the Project) Notice of Preparation. Specifically, two comments are addressed herein pertaining to potential impacts of reduction in discharges from the Big Bear Area Regional Wastewater Agency (BBARWA) plant in Big Bear City to the Lucerne Valley Land Discharge Location (LVDL):

1. Have current and historical discharges to the LVDL contributed to surface or near-surface water flow in the natural wash located approximately 1-mile north of the site?
2. Have discharges to the LVDL caused higher Total Dissolved Solids (TDS) and nitrate concentrations in groundwater beneath the site than otherwise would have occurred absent the discharges?

Potential for Contributions to Surface Flow in the Wash North of the LVDL

It is assumed that the wash in question is the unnamed wash located approximately 0.8-mile northeast of the LVDL (see Figure 1). This wash is ephemeral, meaning that surface water flows in the channel only during periods of extreme above-normal precipitation. A review of historical aerial imagery (i.e. Google Earth) shows that this wash is dry in all historical images available since 1985 although its presence indicates that water has flowed in it periodically.

Based on a review of groundwater level data from wells located north of the LVDL and within or adjacent to the wash, it is not possible that groundwater recharge from surface discharges to the LVDL have caused surface and/or near-surface flow of water in the wash. Available

groundwater level records from 1994 through 2020 indicate that groundwater near the wash has never been shallower than approximately 110 feet below the land surface (see Figure 2). Records from two wells were obtained from the United States Geological Survey (USGS) National Water Information System (NWIS) online water database. Groundwater levels near the wash haven't varied more than approximately 10 feet and for the well with the longest period of record, was approximately the same elevation in 2020 as it was in 1994. As discharges to the LVDL were occurring throughout this time, and as there is no evidence groundwater levels have ever reached the ground surface at the wash, it is not possible that recharge from the LVDL has ever caused surface water flow in the wash.

Potential for Groundwater Quality Impacts from BBARWA Discharges at the LVDL

TDS and nitrate concentrations in BBARWA effluent discharged at the LVDL have historically been lower than the TDS and nitrate concentrations detected in samples from the downgradient monitoring wells at the Site (MW-2 and MW-3).[1] Updated TDS and nitrate data in both the onsite monitoring wells and the BBARWA effluent since 2017 support the previous conclusion that the delivered water from BBARWA is not the source of the high TDS and nitrate concentrations in groundwater (see Figures 3 and 4). TDS concentrations in BBARWA effluent since 2017 show a slightly decreasing trend, while TDS concentrations in the groundwater from downgradient Monitoring Wells MW-2 and MW-3 show a slightly increasing trend (see Figure 3) suggesting the two are not correlated. Further, the downgradient concentrations are higher than the BBARWA effluent concentrations. From a mass balance standpoint, recharge of BBARWA effluent cannot be the source of the higher groundwater TDS concentrations. Similarly, nitrate concentrations in groundwater from all onsite monitoring wells are higher than concentrations in the BBARWA effluent. Thus, while the detection of low concentrations of nitrate in the BBARWA effluent contributes to nitrate in groundwater, the significantly higher nitrate concentrations detected in groundwater beneath the site indicates the BBARWA effluent is only a minor contributor and not the primary source.

REPLENISH BIG BEAR: MODELING OF HIGHER FLOWS AND WITH ZERO TP LOAD

Michael A. Anderson, Ph.D.

Coeur d'Alene, ID

February 24, 2022

Acknowledgement of Credit

This report is financed under the Water Quality, Supply and Infrastructure Improvement Act of 2014, administered by State of California, Department of Water Resources.

Introduction

It was previously noted that water quality was predicted to vary markedly with the level of treatment of added Replenish Big Bear (RBB) recycled water, with Alternative 1 (TIN and TP removal) significantly degrading water quality in Big Bear Lake relative to predicted baseline conditions, while Alternative 2 (70% RO) modestly increased average predicted concentrations of TN, TP and chlorophyll-a, and Alternative 3 (100% RO) was predicted to slightly improve average water quality for the 2009-2019 period (Anderson, 2021, Table 22). Long-term simulations for different hydrologic scenarios yielded similar results, with 100% RO yielding predicted water quality typically comparable to baseline conditions. Notwithstanding, some subtle differences were observed between predicted median baseline concentrations and those for Alternative 3 which assumed steady annual flows of 1920 af/yr of 100% RO water (Anderson, 2021, Table 25).

Recent engineering work indicates that slightly higher inflows, up to 2210 af/yr, can be attained by the Replenish Big Bear project by employing additional brine minimization technology (Table 1). Note that a portion of the water produced by RBB may be discharged to Shay Pond and the earlier "Alternative 3" scenario had excluded those flows (up to 80 af/yr) from the analysis. However, to be conservative for permitting purposes, this analysis is based on discharging all of the recycled water produced to the Lake.

Table 1. Initial and recently updated Replenish Big Bear (RBB) flow projections.

Scenario	**Annual RBB Inflow (af)**	**Daily RBB Inflow (MGD)**
Baseline	0	0
Alternative 3 [(a)]	1920	1.71
High Flow (99% recovery) [(b)]	2210	1.57 – 2.18
Mid Flow (90% recovery) [(b)]	2009	1.42 – 1.98

Notes:

[(a)]Alternative 3 was assessed in the 2021 Lake Analysis and assumed that of the total Replenish Big Bear effluent contribution considered in the Lake Analysis (i.e., 2,000 AFY), 80 AFY would be delivered to Shay Pond. Therefore, only 1,920 AFY would be discharged to the Lake.

[(b)]The updated model analysis assumed that no discharge to Shay Pond would occur and all recycled water would be discharged to the Lake under two different total recovery rates scenarios.

Moreover, deliveries are expected to vary seasonally (Fig 1), thus varying from the earlier "Alternative 3" scenario that assumed uniform flows of 1.71 MGD throughout the year. Inflows to the WWTP are lower in the summer months due to reduced inflow.

Since the Replenish Big Bear project does not have a waste load allocation for total P (TP) in the current TMDL, it is proposing to offset the TP load in the project inflows delivered to Big Bear Lake. While RO is extremely effective at removing dissolved and particulate substances, there nonetheless is a small quantity of TP that is expected to evade treatment (the projected RO effluent concentration is 0.03 mg/L, principally as o-PO_4-P). Elimination of all TP through the treatment process is not practicable, so removal of an equivalent load of TP (up to 200 lbs/yr) from elsewhere in the lake or watershed will be necessary.

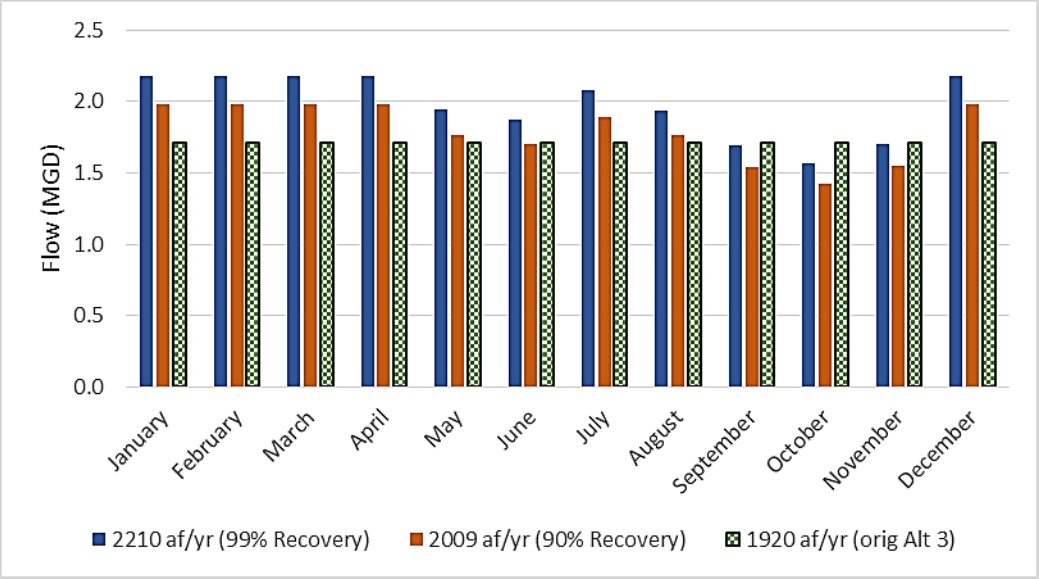

Fig. 1. Monthly flow rates (projected 2040) for Replenish Big Bear under three project inflow scenarios.

In light of these factors, further modeling was conducted to evaluate predicted water quality under these operational scenarios (increased and time-varying flows, with and without TP offset) for comparison with the previously predicted baseline condition and Alternative 3 scenario. Given the complexity of nutrient budgets of lakes, array of possible offset strategies, and equivalence of a given form of nutrient irrespective of its particular origin, TP offset will be modeled as equivalent to 0 influent concentration. This is an approximation that holds when considering whole-lake nutrient budget, but is nonetheless a simplification; depending upon details of offset, hydrodynamic considerations and other factors, some modest lateral gradients in water quality may result. The 50th percentile hydrologic scenario for 2009-2050 was used in this analysis, noting that it includes a wide array of runoff conditions, included extended drought and as well as periods of high runoff. All other hydrologic, meteorological, biological, chemical and sedimentological factors, variables and conditions were identical to those used in prior simulations of long-term future conditions (Anderson, 2021).

Results

Long-term averaged predicted concentrations of TDS, TIN, total P, total N and chlorophyll-a were lower with addition of RBB water compared with predicted baseline conditions (no supplementation) (Table 2). For reference, TMDL target values are included in the table. Focusing on chlorophyll-a as the key response target, baseline conditions were predicted to yield growing-season average chlorophyll-a concentration that slightly exceeded (by 0.1 µg/L) the TMDL target value of 14 µg/L, while Alternative 3 matched the target value, and larger inputs of RBB inflow that varied seasonally (Fig. 1) yielded values below baseline and TMDL target values (Table 2). Zeroing out the load of TP in RBB inflow yielded further reductions in chlorophyll-a; larger inflow volumes with reduced summer flows and no net TP loading were predicted to yield growing season average chlorophyll-a concentrations as low as 9.5 - 10.2 µg/L, significantly below predicted baseline and TMDL concentrations (Table 2).

Table 2. Long-term average predicted concentrations of total P, total N and chlorophyll-a in Big Bear Lake under different operational scenarios (total P and total N expressed as annual average concentrations; chlorophyll-a shown as growing season average concentrations).

Operational Scenario (all at 50th % hydrology)	**TDS (mg/L)**	**TIN (mg/L**	**Total P (µg/L)**	**Total N (mg/L)**	**Chlorophyll-a (µg/L)**
Baseline	**195**	**0.069**	**47.7**	**1.15**	**14.1**
Alternative 3 (1920 af)	182	0.052	43.3	1.07	14.0
2210 af (99% recovery)	**179**	**0.045**	**42.3**	**1.04**	**13.1**
2009 af (90% recovery)	**180**	**0.041**	**43.4**	**1.06**	**12.9**
2210 af + 0 total P	179	0.072	39.9	1.00	10.2
2009 af + 0 total P	180	0.040	40.9	1.00	9.5
TMDL target			***35.0***		***14.0***

Supplementation with RBB inflow also lowered concentrations of total P and total N relative to predicted baseline levels (Table 2). This is consistent with the reduced concentrations of total N and total P (and most dissolved forms of N and P) in RO water relative to watershed runoff concentrations (Anderson, 2021, Table 20), with concentrations projected to be only 40% - 80% of average watershed runoff concentrations (Anderson, 2021, Table 21). Interestingly, zeroing out the influent TP concentration not only lowered the predicted average total P concentration but also reduced the predicted total N concentrations, highlighting the complex biogeochemical coupling of these two key nutrients. While it is important to recognize the uncertainty in model predictions, it is nonetheless noteworthy that revised project flows, with varying seasonal flow and TP offset, yielded average chlorophyll-a concentrations significantly below baseline and TMDL values and also yielded long-term average TN concentrations approaching or reaching 1 mg/L, which is being considered by the Regional Water Board. Predicted long-term average TP concentrations remained above the TMDL target, but were nonetheless meaningfully lower than the predicted baseline level (Table 2). Average TDS and TIN concentrations were also lower than predicted baseline conditions (with exception of 2210 af + 0 TP, where a period of higher NO_3-N was predicted).

Inter-annual differences in water quality are nonetheless expected to persist. Cumulative distributions functions (CDFs) highlight the predicted wide range in annual and growing season average concentrations (Fig. 2). While addition of RBB inflow shifted CDFs to lower annual average total P and total N concentrations and growing season average chlorophyll-a concentrations, wide ranges in predicted concentrations remained in place (Fig. 2). Thus, the growing season average chlorophyll-a target of 14 µg/L was predicted to be exceeded about 53% of the time under baseline conditions, and exceeded about 41% and 31% of the time with RBB inflows of 2210 af/yr without and with TP offset, respectively (Fig. 2c; Table 3). Results for all scenarios are summarized in Table 3.

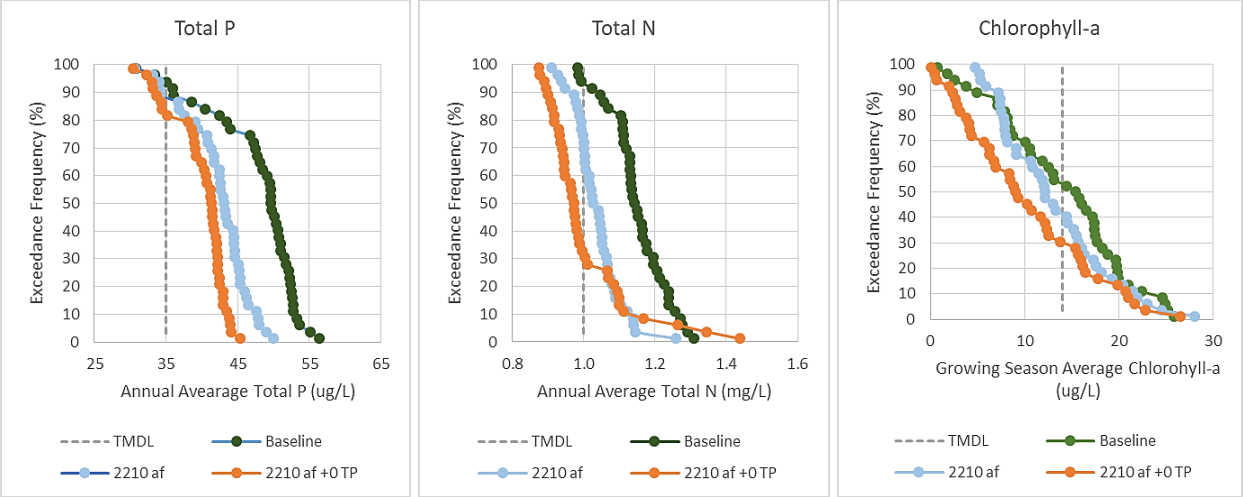

Fig. 2. Cumulative distribution functions for predicted annual total P and total N concentrations and growing season average chlorophyll-a concentrations for baseline condition and with 2210 af RBB inflow with and without TP offset.

Table 3. Predicted frequency of exceeding TMDL target under baseline conditions and different RBB inflow and TP offset scenarios (annual average or growing season average basis). Observed annual exceedance frequencies for 2009-19 period shown in parentheses under Baseline.

Variable	**Baseline**	**1920 af**	**2210 af**	**2210 af+0 TP**	**2009 af**	**2009 af+0 TP**
Total P	94 % (100%)	87 %	87 %	82 %	91 %	90 %

EXECUTIVE SUMMARY

ES.1 SUMMARY OF FINDINGS

The results of this *Replenish Big Bear Program Air Quality Impact Analysis* (AQIA) are summarized below based on the significance criteria in Section 3 of this report consistent with Appendix G of the California Environmental Quality Act (CEQA) Guidelines (1). Table ES-1 shows the findings of significance for each potential air quality impact under CEQA before and after any required mitigation measures (MM) described below.

TABLE ES-1: SUMMARY OF CEQA SIGNIFICANCE FINDINGS

Analysis	Report Section	Significance Findings	
		Unmitigated	Mitigated
Regional Construction Emissions	3.4	*Potentially Significant*	*Less Than Significant*
Localized Construction Emissions	3.7	*Potentially Significant*	*Less Than Significant*
Regional Operational Emissions	3.5	*Less Than Significant*	*n/a*
Localized Operational Emissions	3.8	*Less Than Significant*	*n/a*
CO "Hot Spot" Analysis	3.9	*Less Than Significant*	*n/a*

Odors	3.12	*Less Than Significant*	*n/a*
Cumulative Impacts	3.13	*Potentially Significant*	*Less Than Significant*

ES.2 REGULATORY REQUIREMENTS

There are numerous requirements that development projects must comply with by law, and that were put in place by federal, State, and local regulatory agencies for the improvement of air quality.

Any operation or activity that might cause the emission of any smoke, fly ash, dust, fumes, vapors, gases, or other forms of air pollution, which can cause damage to human health, vegetation, or

other forms of property, or can cause excessive soiling on any other parcel shall conform to the requirements of the SCAQMD.

SCAQMD RULES

SCAQMD Rules that are currently applicable during construction activity for this Project are described below.

SCAQMD RULE 402

A person shall not discharge from any source whatsoever such quantities of air contaminants or other material that cause injury, detriment, nuisance, or annoyance to any considerable number of persons or to the public, or that endanger the comfort, repose, health, or safety of any such persons or the public, or that cause, or have a natural tendency to cause, injury or damage to business or property. The provisions of this rule do not apply to odors emanating from agricultural operations necessary for the growing of crops or the raising of fowl or animals.

Odor Emissions. All uses shall be operated in a manner such that no offensive odor is perceptible at or beyond the property line of that use.

SCAQMD RULE 403

This rule is intended to reduce the amount of particulate matter entrained in the ambient air as a result of anthropogenic (human-made) fugitive dust sources by requiring actions to prevent and reduce fugitive dust emissions. Rule 403 applies to any activity or human-made condition capable of generating fugitive dust and requires best available control measures to be applied to earth moving and grading activities.

The contractor shall adhere to the following applicable measures of Rule 403 including, but not limited to:

- All clearing, grading, earth-moving, or excavation activities shall cease when winds exceed 25 miles per hour (mph) per SCAQMD guidelines in order to limit fugitive dust emissions.
- The contractor shall ensure that all disturbed unpaved roads and disturbed areas within the Project are watered at least three (3) times daily during dry weather. Watering, with complete coverage of disturbed areas, shall occur at least three times a day, preferably in the mid-morning, afternoon, and after work is done for the day.
- All access points to the Project site shall have track out devices installed.
- The contractor shall ensure that traffic speeds on unpaved roads and Project site areas are limited to 15 mph or less

Dust Control, Operations. Any operation or activity that might cause the emission of any smoke, fly ash, dust, fumes, vapors, gases, or other forms of air pollution, which can cause damage to human health, vegetation, or other forms of property, or can cause excessive soiling on any other parcel, shall conform to the requirements of the SCAQMD.

SCAQMD RULE 1113

This rule serves to limit the VOC content of architectural coatings used on projects in the SCAQMD. Any person who supplies, sells, offers for sale, or manufactures any architectural coating for use on projects.

ES.3 CONSTRUCTION-SOURCE MITIGATION MEASURES

MM AQ-1

When using construction equipment greater than 150 horsepower (>150 hp), the Construction Contractor shall ensure that off-road diesel construction equipment complies with the Environmental Protection Agency (EPA)/California Air Resources Board (CARB) Tier 4 emissions standards or equivalent and shall ensure that all construction equipment is tuned and maintained in accordance with the manufacturer's specifications.

1 INTRODUCTION

This report presents the results of the AQIA prepared by Urban Crossroads, Inc., for the proposed Replenish Big Bear Program (Project). The purpose of this AQIA is to evaluate the potential impacts to air quality associated with construction and operation of the proposed Project and, if warranted, recommend measures to mitigate impacts considered potentially significant in comparison to thresholds established by the SCAQMD.

1.1 SITE LOCATION

The Project site is located within the Big Bear Valley Groundwater Management Zone (GMZ or Basin). Big Bear Lake and Baldwin Lake are located in the middle of this Basin. The overall project area consists of the Valley in the County of San Bernardino, as shown on Exhibit 1-A.

1.2 PROJECT DESCRIPTION

The proposed Project includes upgrades and additions to Big Bear Area Regional Wastewater Agency's (BBARWA) wastewater treatment plant (WWTP) to produce purified water through full advanced treatment to protect the receiving waters and their beneficial uses. The Replenish Big Bear Program would upgrade BBARWA's WWTP to produce full advanced treated water that would be retained within the Big Bear Valley watershed to be used to increase the sustainability of local water supplies, consequently, wastewater currently delivered to Lucerne Valley will be modified. The proposed Project consists of construction and operation of the various facilities which are separated into five project categories: 1) Replenish Big Bear Component 1: Lake Discharge Pipeline Alignment; 2) Replenish Big Bear Component 2: Shay Pond; 3) Replenish Big Bear Component 3: Evaporation Pond; 4) Replenish Big Bear Component 4: BBARWA WWTP Upgrades; and 5) Replenish Big Bear Component 5: Sand Canyon.

REPLENISH BIG BEAR COMPONENT 1: BBARWA WWTP UPGRADES

This Replenish Big Bear Component includes upgrades to the BBARWA WWTP, to include 2.2 MGD of full advanced treatment, producing up to 2,210 AFY of purified water. The upgrades include the construction of a 40,000 SF building which would provide the following upgrades and new construction in order of process flow:

- Upgrades to the Oxidation Ditches
- New Denitrification Filter
- New UF and RO filtration membranes
- New UV Disinfection
- New AOP
- New Pellet Reactor: 0.22 MGD

The BBARWA WWTP Treatment Upgrades also includes the installation of about 1,350 LF of brine pipeline anticipated to be sized between 8" to 10" from the pellet reactor to the solar evaporation ponds. Additionally, the BBARWA WWTP Treatment Upgrades also includes installation of a 50 gpm brine pump station and a 1,520 gpm pump station at the BBARWA WWTP to pump purified water to Shay Pond and Stanfield Marsh.

REPLENISH BIG BEAR COMPONENT 2: LAKE DISCHARGE PIPELINE ALIGNMENT

The Replenish Big Bear Program would ultimately install a pipeline utilizing one of three alignments from the WWTP to Stanfield Marsh in the amount of about 19,940 LF sized at 12" in diameter.

REPLENISH BIG BEAR COMPONENT 3: SHAY POND CONVEYANCE PIPELINE

The Replenish Big Bear Program would ultimately install about 710 LF of 4" pipeline to reach Shay Pond from either an existing pipeline or a new 6" pipeline that would be 5,600 LF. As such, this Replenish Big Bear Component includes the installation of up to 6,310 LF of conveyance pipeline.

REPLENISH BIG BEAR COMPONENT 4: EVAPORATION POND

The Replenish Big Bear Program would include between 23 and 57 acres of evaporation ponds at the BBARWA WWTP site. The ponds would be segmented into different storage basins to allow for evaporation of the brine stream in a cycle of filling with brine, allowing the brine to evaporate, and then removing remaining brine. This Replenish Big Bear Component includes the installation of up to 2 monitoring wells.

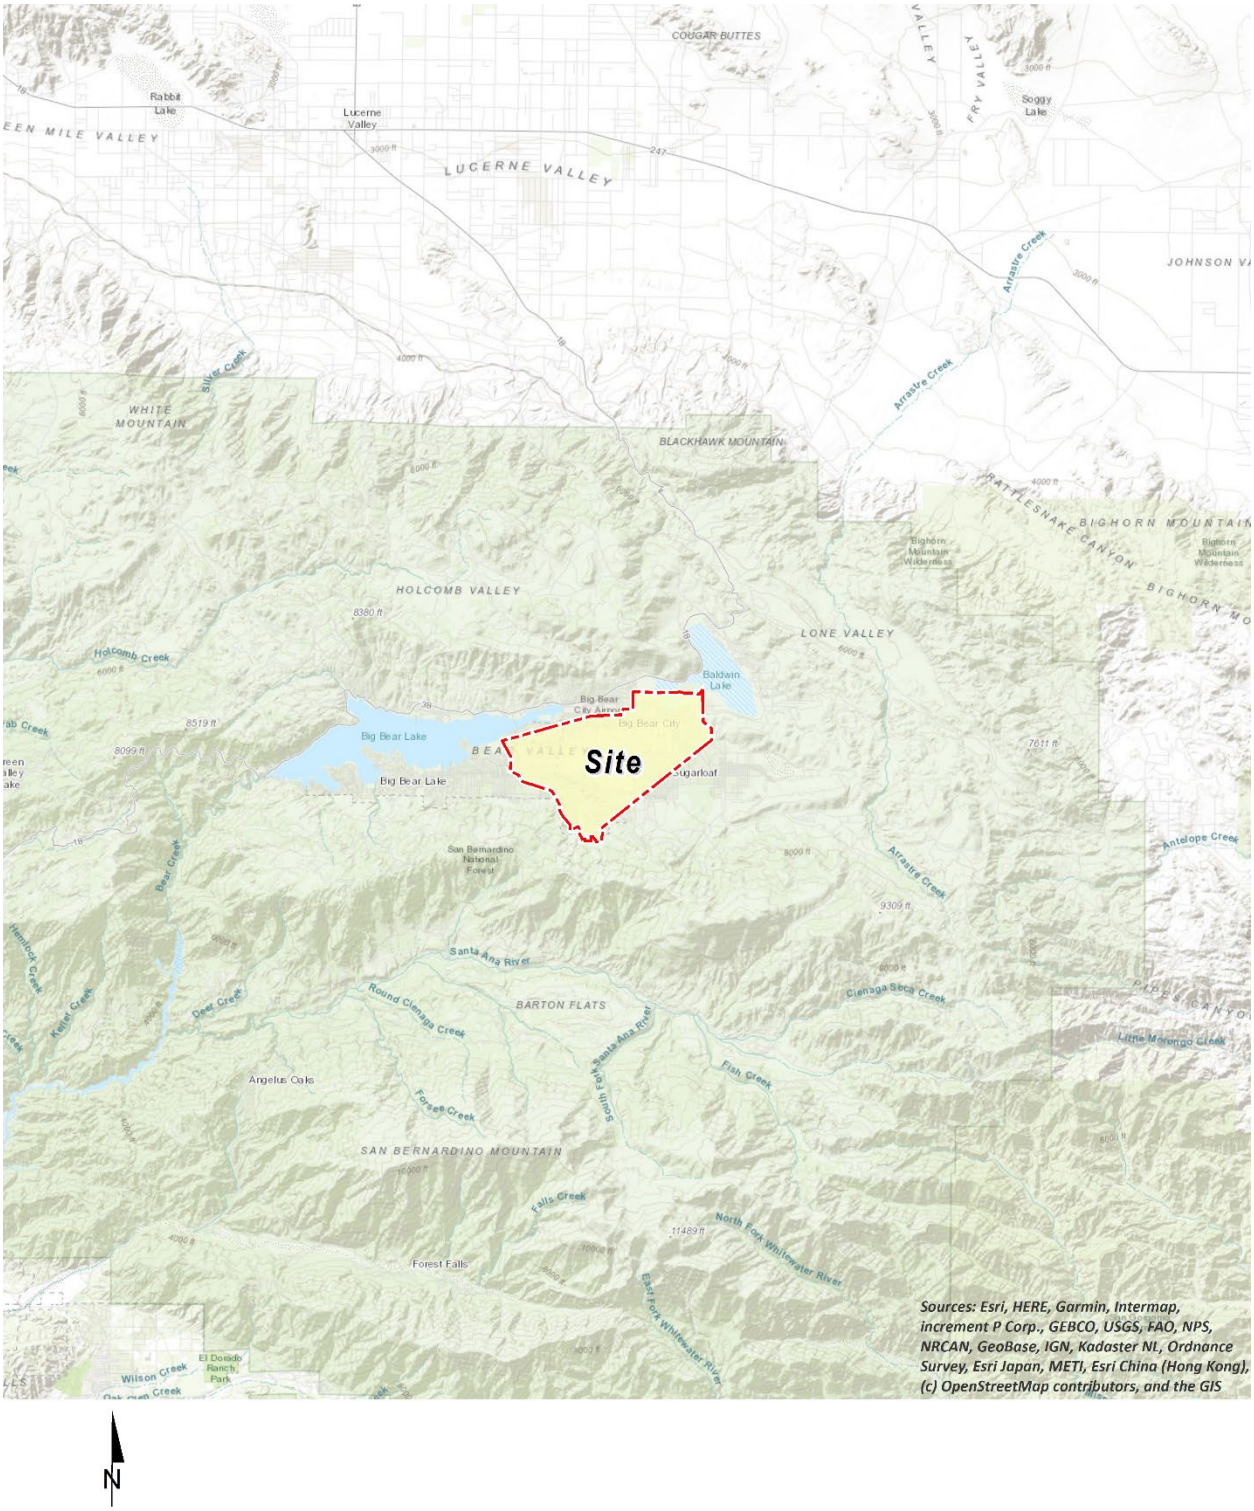
REPLENISH BIG BEAR COMPONENT 5: SAND CANYON

The Sand Canyon groundwater recharge project involves extracting Project water stored in the Lake to a temporary storage pond using existing infrastructure owned by a local resort. The Project water will then be pumped and conveyed to the Sand Canyon recharge area using a new pump station and pipeline.

As part of the Replenish Big Bear Program, the following will be constructed:

- A new 471 gpm pump station near the snowmaking pond, at the BBLDWP Sand Canyon Well site, to convey water to Sand Canyon.
- A new 8-inch pipeline that will discharge into Sand Canyon and will be approximately 7,200 feet in length.
- Two monitoring wells for groundwater recharge at Sand Canyon, as required by the future discharge permit.
- Installation of erosion control using rip rap or similar erosion control methods, at Sand Canyon

EXHIBIT 1-A: PROJECT LOCATION MAP



This page intentionally left blank

2 AIR QUALITY SETTING

This section provides an overview of the existing air quality conditions in the Project area and region.

2.1 SOUTH COAST AIR BASIN

The Project site is located in the South Coast Air Basin (SCAB) within the jurisdiction of SCAQMD (2). The SCAQMD was created by the 1977 Lewis-Presley Air Quality Management Act, which merged four county air pollution control bodies into one regional district. Under the Act, the SCAQMD is responsible for bringing air quality in areas under its jurisdiction into conformity with federal and state air quality standards. As previously stated, the Project site is located within the SCAB, a 6,745-square mile subregion of the SCAQMD, which includes portions of Los Angeles, Riverside, and San Bernardino Counties, and all of Orange County.

The SCAB is bounded by the Pacific Ocean to the west and the San Gabriel, San Bernardino, and San Jacinto Mountains to the north and east. The Los Angeles County portion of the Mojave Desert Air Basin is bounded by the San Gabriel Mountains to the south and west, the Los Angeles / Kern County border to the north, and the Los Angeles / San Bernardino County border to the east. The Riverside County portion of the Salton Sea Air Basin is bounded by the San Jacinto Mountains in the west and spans eastward up to the Palo Verde Valley.

2.2 REGIONAL CLIMATE

The regional climate has a substantial influence on air quality in the SCAB. In addition, the temperature, wind, humidity, precipitation, and amount of sunshine influence the air quality.

The annual average temperatures throughout the SCAB vary from the low to middle 60s degrees Fahrenheit (°F). Due to a decreased marine influence, the eastern portion of the SCAB shows greater variability in average annual minimum and maximum temperatures. January is the coldest month throughout the SCAB, with average minimum temperatures of 47°F in downtown Los Angeles and 36°F in San Bernardino. All portions of the SCAB have recorded maximum temperatures above 100°F.

Although the climate of the SCAB can be characterized as semi-arid, the air near the land surface is quite moist on most days because of the presence of a marine layer. This shallow layer of sea air is an important modifier of SCAB climate. Humidity restricts visibility in the SCAB, and the conversion of sulfur dioxide (SO_2) to sulfates (SO_4) is heightened in air with high relative humidity. The marine layer provides an environment for that conversion process, especially during the spring and summer months. The annual average relative humidity within the SCAB is 71% along the coast and 59% inland. Since the ocean effect is dominant, periods of heavy early morning fog are frequent and low stratus clouds are a characteristic feature. These effects decrease with distance from the coast.

More than 90% of the SCAB's rainfall occurs from November through April. The annual average rainfall varies from approximately nine inches in Riverside to fourteen inches in downtown Los

Angeles. Monthly and yearly rainfall totals are extremely variable. Summer rainfall usually consists of widely scattered thunderstorms near the coast and slightly heavier shower activity in the eastern portion of the SCAB with frequency being higher near the coast.

Due to its generally clear weather, about three-quarters of available sunshine is received in the SCAB. The remaining one-quarter is absorbed by clouds. The ultraviolet portion of this abundant radiation is a key factor in photochemical reactions. On the shortest day of the year there are approximately 10 hours of possible sunshine, and on the longest day of the year there are approximately 14½ hours of possible sunshine.

The importance of wind to air pollution is considerable. The direction and speed of the wind determines the horizontal dispersion and transport of the air pollutants. During the late autumn to early spring rainy season, the SCAB is subjected to wind flows associated with the traveling storms moving through the region from the northwest. This period also brings five to ten periods of strong, dry offshore winds, locally termed "Santa Anas" each year. During the dry season, which coincides with the months of maximum photochemical smog concentrations, the wind flow is bimodal, typified by a daytime onshore sea breeze and a nighttime offshore drainage wind. Summer wind flows are created by the pressure differences between the relatively cold ocean and the unevenly heated and cooled land surfaces that modify the general northwesterly wind circulation over southern California. Nighttime drainage begins with the radiational cooling of the mountain slopes. Heavy, cool air descends the slopes and flows through the mountain passes and canyons as it follows the lowering terrain toward the ocean. Another characteristic wind regime in the SCAB is the "Catalina Eddy," a low level cyclonic (counterclockwise) flow centered over Santa Catalina Island which results in an offshore flow to the southwest. On most spring and summer days, some indication of an eddy is apparent in coastal sections.

In the SCAB, there are two distinct temperature inversion structures that control vertical mixing of air pollution. During the summer, warm high-pressure descending (subsiding) air is undercut by a shallow layer of cool marine air. The boundary between these two layers of air is a persistent marine subsidence/inversion. This boundary prevents vertical mixing which effectively acts as an impervious lid to pollutants over the entire SCAB. The mixing height for the inversion structure is normally situated 1,000 to 1,500 feet above mean sea level.

A second inversion-type forms in conjunction with the drainage of cool air off the surrounding mountains at night followed by the seaward drift of this pool of cool air. The top of this layer forms a sharp boundary with the warmer air aloft and creates nocturnal radiation inversions. These inversions occur primarily in the winter, when nights are longer and onshore flow is weakest. They are typically only a few hundred feet above mean sea level. These inversions effectively trap pollutants, such as nitrogen oxides (NO_X) and carbon monoxide (CO) from vehicles, as the pool of cool air drifts seaward. Winter is therefore a period of high levels of primary pollutants along the coastline.

2.3 WIND PATTERNS AND PROJECT LOCATION

The distinctive climate of the Project area and the SCAB is determined by its terrain and geographical location. The SCAB is located in a coastal plain with connecting broad valleys and

low hills, bounded by the Pacific Ocean in the southwest quadrant with high mountains forming the remainder of the perimeter.

Wind patterns across the south coastal region are characterized by westerly and southwesterly onshore winds during the day and easterly or northeasterly breezes at night. Winds are characteristically light although the speed is somewhat greater during the dry summer months than during the rainy winter season.

2.4 CRITERIA POLLUTANTS

Criteria pollutants are pollutants that are regulated through the development of human health based and/or environmentally based criteria for setting permissible levels. Criteria pollutants, their typical sources, and health effects are identified below (3):

TABLE 2-1: CRITERIA POLLUTANTS

Criteria Pollutant	Description	Sources	Health Effects
CO	CO is a colorless, odorless gas produced by the incomplete combustion of carbon-containing fuels, such as gasoline or wood. CO concentrations tend to be the highest during the winter morning, when little to no wind and surface-based inversions trap the pollutant at ground levels. Because CO is emitted directly from internal combustion engines, unlike ozone (O_3), motor vehicles operating at slow speeds are the primary source of CO in the SCAB. The highest ambient CO concentrations are generally found near congested transportation corridors and intersections.	Any source that burns fuel such as automobiles, trucks, heavy construction equipment, farming equipment and residential heating.	Individuals with a deficient blood supply to the heart are the most susceptible to the adverse effects of CO exposure. The effects observed include earlier onset of chest pain with exercise, and electrocardiograph changes indicative of decreased oxygen (O_2) supply to the heart. Inhaled CO has no direct toxic effect on the lungs but exerts its effect on tissues by interfering with O_2 transport and competing with O_2 to combine with hemoglobin present in the blood to form carboxyhemoglobin (COHb). Hence, conditions with an increased demand for O_2 supply can be adversely affected by exposure to CO. Individuals most at risk include fetuses, patients with diseases involving heart and blood vessels, and patients with chronic hypoxemia (O_2 deficiency) as seen at high altitudes.

Criteria Pollutant	Description	Sources	Health Effects
SO_2	SO_2 is a colorless, extremely irritating gas or liquid. It enters the atmosphere as a pollutant mainly as a result of burning high sulfur-content fuel oils and coal and from chemical processes occurring at chemical plants and refineries. When SO_2 oxidizes in the atmosphere, it forms SO_4. Collectively, these pollutants are referred to as sulfur oxides (SO_X).	Coal or oil burning power plants and industries, refineries, diesel engines	A few minutes of exposure to low levels of SO_2 can result in airway constriction in some asthmatics, all of whom are sensitive to its effects. In asthmatics, increase in resistance to air flow, as well as reduction in breathing capacity leading to severe breathing difficulties, are observed after acute exposure to SO_2. In contrast, healthy individuals do not exhibit similar acute responses even after exposure to higher concentrations of SO_2. Animal studies suggest that despite SO_2 being a respiratory irritant, it does not cause substantial lung injury at ambient concentrations. However, very high levels of exposure can cause lung edema (fluid accumulation), lung tissue damage, and sloughing off of cells lining the respiratory tract. Some population-based studies indicate that the mortality and morbidity effects associated with fine particles show a similar association with ambient SO_2 levels. In these studies, efforts to separate the effects of SO_2 from those of fine particles have not been successful. It is not clear whether the two pollutants act synergistically, or one pollutant alone is the predominant factor.

Criteria Pollutant	Description	Sources	Health Effects
NO_X	NO_X consist of nitric oxide (NO), nitrogen dioxide (NO_2) and nitrous oxide (N_2O) and are formed when nitrogen (N_2) combines with O_2. Their lifespan in the atmosphere ranges from one to seven days for NO and N_2O, to 170 years for nitrous oxide. NO_X is typically created during combustion processes and are major contributors to smog formation and acid deposition. NO_2 is a criteria air pollutant and may result in numerous adverse health effects; it absorbs blue light, resulting in a brownish-red cast to the atmosphere and reduced visibility. Of the seven types of nitrogen oxide compounds, NO_2 is the most abundant in the atmosphere. As ambient concentrations of NO_2 are related to traffic density, commuters in heavy traffic may be exposed to higher concentrations of NO_2 than those indicated by regional monitoring station.	Any source that burns fuel such as automobiles, trucks, heavy construction equipment, farming equipment and residential heating.	Population-based studies suggest that an increase in acute respiratory illness, including infections and respiratory symptoms in children (not infants), is associated with long-term exposure to NO_2 at levels found in homes with gas stoves, which are higher than ambient levels found in Southern California. Increase in resistance to air flow and airway contraction is observed after short-term exposure to NO_2 in healthy subjects. Larger decreases in lung functions are observed in individuals with asthma or chronic obstructive pulmonary disease (e.g., chronic bronchitis, emphysema) than in healthy individuals, indicating a greater susceptibility of these sub-groups. In animals, exposure to levels of NO_2 considerably higher than ambient concentrations result in increased susceptibility to infections, possibly due to the observed changes in cells involved in maintaining immune functions. The severity of lung tissue damage associated with high levels of O_3 exposure increases when animals are exposed to a combination of O_3 and NO_2.
O_3	O_3 is a highly reactive and unstable gas that is formed when VOCs and NO_X, both byproducts of internal combustion engine exhaust, undergo slow photochemical reactions in the presence of sunlight. O_3 concentrations are generally	Formed when reactive organic gases (ROG) and NO_X react in the presence of sunlight. ROG sources	Individuals exercising outdoors, children, and people with preexisting lung disease, such as asthma and chronic pulmonary lung disease, are considered to be the most susceptible sub-groups for O_3 effects. Short-

Criteria Pollutant	Description	Sources	Health Effects
	highest during the summer months when direct sunlight, light wind, and warm temperature conditions are favorable to the formation of this pollutant.	include any source that burns fuels, (e.g., gasoline, natural gas, wood, oil) solvents, petroleum processing and storage and pesticides.	term exposure (lasting for a few hours) to O_3 at levels typically observed in Southern California can result in breathing pattern changes, reduction of breathing capacity, increased susceptibility to infections, inflammation of the lung tissue, and some immunological changes. Elevated O_3 levels are associated with increased school absences. In recent years, a correlation between elevated ambient O_3 levels and increases in daily hospital admission rates, as well as mortality, has also been reported. An increased risk for asthma has been found in children who participate in multiple outdoor sports and live in communities with high O_3 levels. O_3 exposure under exercising conditions is known to increase the severity of the responses described above. Animal studies suggest that exposure to a combination of pollutants that includes O_3 may be more toxic than exposure to O_3 alone. Although lung volume and resistance changes observed after a single exposure diminish with repeated exposures, biochemical and cellular changes appear to persist, which can lead to subsequent lung structural changes.
Particulate Matter	PM_{10}: A major air pollutant consisting of tiny solid or liquid particles of soot, dust, smoke, fumes, and aerosols. Particulate matter pollution is a major cause of reduce visibility (haze) which is	Sources of PM_{10} include road dust, windblown dust and construction. Also formed from other pollutants (acid	A consistent correlation between elevated ambient fine particulate matter (PM_{10} and $PM_{2.5}$) levels and an increase in mortality rates, respiratory infections,

Criteria Pollutant	Description	Sources	Health Effects
	caused by the scattering of light and consequently the significant reduction air clarity. The size of the particles (10 microns or smaller, about 0.0004 inches or less) allows them to easily enter the lungs where they may be deposited, resulting in adverse health effects. Additionally, it should be noted that PM_{10} is considered a criteria air pollutant. $PM_{2.5}$: A similar air pollutant to PM_{10} consisting of tiny solid or liquid particles which are 2.5 microns or smaller (which is often referred to as fine particles). These particles are formed in the atmosphere from primary gaseous emissions that include SO_4 formed from SO_2 release from power plants and industrial facilities and nitrates that are formed from NO_X release from power plants, automobiles and other types of combustion sources. The chemical composition of fine particles highly depends on location, time of year, and weather conditions. $PM_{2.5}$ is a criteria air pollutant.	rain, NO_X, SO_X, organics). Incomplete combustion of any fuel. $PM_{2.5}$ comes from fuel combustion in motor vehicles, equipment and industrial sources, residential and agricultural burning. Also formed from reaction of other pollutants (acid rain, NO_X, SO_X, organics).	number and severity of asthma attacks and the number of hospital admissions has been observed in different parts of the United States and various areas around the world. In recent years, some studies have reported an association between long-term exposure to air pollution dominated by fine particles and increased mortality, reduction in lifespan, and an increased mortality from lung cancer. Daily fluctuations in $PM_{2.5}$ concentration levels have also been related to hospital admissions for acute respiratory conditions in children, to school and kindergarten absences, to a decrease in respiratory lung volumes in normal children, and to increased medication use in children and adults with asthma. Recent studies show lung function growth in children is reduced with long term exposure to particulate matter. The elderly, people with pre-existing respiratory or cardiovascular disease, and children appear to be more susceptible to the effects of high levels of PM_{10} and $PM_{2.5}$.
VOC	VOCs are hydrocarbon compounds (any compound containing various combinations of hydrogen and carbon atoms) that exist in the ambient air. VOCs contribute to the formation of smog through atmospheric photochemical reactions and/or may be toxic. Compounds of carbon (also known as organic compounds) have different levels	Organic chemicals are widely used as ingredients in household products. Paints, varnishes and wax all contain organic solvents, as do many cleaning, disinfecting, cosmetic,	Breathing VOCs can irritate the eyes, nose and throat, can cause difficulty breathing and nausea, and can damage the central nervous system as well as other organs. Some VOCs can cause cancer. Not all VOCs have all these health effects, though many have several.

Criteria Pollutant	Description	Sources	Health Effects
	of reactivity; that is, they do not react at the same speed or do not form O_3 to the same extent when exposed to photochemical processes. VOCs often have an odor, and some examples include gasoline, alcohol, and the solvents used in paints. Exceptions to the VOC designation include CO, carbon dioxide, carbonic acid, metallic carbides or carbonates, and ammonium carbonate. VOCs are a criteria pollutant since they are a precursor to O_3, which is a criteria pollutant. The terms VOC and ROG (see below) interchangeably.	degreasing and hobby products. Fuels are made up of organic chemicals. All of these products can release organic compounds while you are using them, and, to some degree, when they are stored.	
ROG	Similar to VOC, ROGs are also precursors in forming O_3 and consist of compounds containing methane, ethane, propane, butane, and longer chain hydrocarbons, which are typically the result of some type of combustion/decomposition process. Smog is formed when ROG and NO_X react in the presence of sunlight. ROGs are a criteria pollutant since they are a precursor to O_3, which is a criteria pollutant. The terms ROG and VOC (see previous) interchangeably.	Sources similar to VOCs.	Health effects similar to VOCs.
Lead (Pb)	Pb is a heavy metal that is highly persistent in the environment and is considered a criteria pollutant. In the past, the primary source of Pb in the air was emissions from vehicles burning leaded gasoline. The major sources of Pb emissions are ore and metals processing, particularly Pb smelters, and piston-engine aircraft operating on leaded aviation gasoline. Other stationary sources include waste incinerators, utilities, and	Metal smelters, resource recovery, leaded gasoline, deterioration of Pb paint.	Fetuses, infants, and children are more sensitive than others to the adverse effects of Pb exposure. Exposure to low levels of Pb can adversely affect the development and function of the central nervous system, leading to learning disorders, distractibility, inability to follow simple commands, and lower intelligence quotient. In adults, increased Pb levels are

Criteria Pollutant	Description	Sources	Health Effects
	lead-acid battery manufacturers. It should be noted that the Project does not include operational activities such as metal processing or Pb acid battery manufacturing. As such, the Project is not anticipated to generate a quantifiable amount of Pb emissions.		associated with increased blood pressure. Pb poisoning can cause anemia, lethargy, seizures, and death; although it appears that there are no direct effects of Pb on the respiratory system. Pb can be stored in the bone from early age environmental exposure, and elevated blood Pb levels can occur due to breakdown of bone tissue during pregnancy, hyperthyroidism (increased secretion of hormones from the thyroid gland) and osteoporosis (breakdown of bony tissue). Fetuses and breast-fed babies can be exposed to higher levels of Pb because of previous environmental Pb exposure of their mothers.
Odor	Odor means the perception experienced by a person when one or more chemical substances in the air come into contact with the human olfactory nerves (4).	Odors can come from many sources including animals, human activities, industry, natures, and vehicles.	Offensive odors can potentially affect human health in several ways. First, odorant compounds can irritate the eye, nose, and throat, which can reduce respiratory volume. Second, studies have shown that the VOCs that cause odors can stimulate sensory nerves to cause neurochemical changes that might influence health, for instance, by compromising the immune system. Finally, unpleasant odors can trigger memories or attitudes linked to unpleasant odors, causing cognitive and emotional effects such as stress.

2.5 EXISTING AIR QUALITY

Existing air quality is measured at established SCAQMD air quality monitoring stations. Monitored air quality is evaluated in the context of ambient air quality standards. These standards are the levels of air quality that are considered safe, with an adequate margin of safety, to protect the public health and welfare. National Ambient Air Quality Standards (NAAQS) and California Ambient Air Quality Standards (CAAQS) currently in effect are shown in Table 2-2 (5).

The determination of whether a region's air quality is healthful or unhealthful is determined by comparing contaminant levels in ambient air samples to the state and federal standards. At the time of this AQIA, the most recent state and federal standards are presented in Table 2-2. The air quality in a region is considered to be in attainment if the measured ambient air pollutant levels for O_3, CO (except 8-hour Lake Tahoe), SO_2 (1 and 24 hour), NO_2, PM_{10}, and $PM_{2.5}$ are not to be exceeded. All others are not to be equaled or exceeded. It should be noted that the three-year period is presented for informational purposes and is not the basis for how attainment status is determined. Attainment status for a pollutant means that the SCAB meets the standards set by the U.S. Environmental Protection Agency (EPA) or the California EPA (CalEPA). Conversely, nonattainment means that an area has monitored air quality that does not meet the NAAQS or CAAQS. A State Implementation Plan (SIP) is required by the federal Clean Air Act (CAA) for area that are designated non-attainment under the NAAQS. A SIP outlines the measures that a state will take to improve air quality in the area designated nonattainment. Once a nonattainment area meets the standards and additional redesignation requirements, the EPA designates the area as a maintenance area (6).

TABLE 2-2: AMBIENT AIR QUALITY STANDARDS (1 OF 2)

Ambient Air Quality Standards						
Pollutant	**Averaging Time**	**California Standards [1]**		**National Standards [2]**		
		Concentration [3]	**Method [4]**	**Primary [3,5]**	**Secondary [3,6]**	**Method [7]**
Ozone (O_3)[8]	1 Hour	0.09 ppm (180 µg/m^3)	Ultraviolet Photometry	—	Same as Primary Standard	Ultraviolet Photometry
	8 Hour	0.070 ppm (137 µg/m^3)		0.070 ppm (137 µg/m^3)		
Respirable Particulate Matter (PM10)[9]	24 Hour	50 µg/m^3	Gravimetric or Beta Attenuation	150 µg/m^3	Same as Primary Standard	Inertial Separation and Gravimetric Analysis
	Annual Arithmetic Mean	20 µg/m^3		—		
Fine Particulate Matter (PM2.5)[9]	24 Hour	—	—	35 µg/m^3	Same as Primary Standard	Inertial Separation and Gravimetric Analysis
	Annual Arithmetic Mean	12 µg/m^3	Gravimetric or Beta Attenuation	12.0 µg/m^3	15 µg/m^3	
Carbon Monoxide (CO)	1 Hour	20 ppm (23 mg/m^3)	Non-Dispersive Infrared Photometry (NDIR)	35 ppm (40 mg/m^3)	—	Non-Dispersive Infrared Photometry (NDIR)
	8 Hour	9.0 ppm (10 mg/m^3)		9 ppm (10 mg/m^3)	—	
	8 Hour (Lake Tahoe)	6 ppm (7 mg/m^3)		—	—	
Nitrogen Dioxide (NO_2)[10]	1 Hour	0.18 ppm (339 µg/m^3)	Gas Phase Chemiluminescence	100 ppb (188 µg/m^3)	—	Gas Phase Chemiluminescence
	Annual Arithmetic Mean	0.030 ppm (57 µg/m^3)		0.053 ppm (100 µg/m^3)	Same as Primary Standard	
Sulfur Dioxide (SO_2)[11]	1 Hour	0.25 ppm (655 µg/m^3)	Ultraviolet Fluorescence	75 ppb (196 µg/m^3)	—	Ultraviolet Flourescence; Spectrophotometry (Pararosaniline Method)
	3 Hour	—		—	0.5 ppm (1300 µg/m^3)	
	24 Hour	0.04 ppm (105 µg/m^3)		0.14 ppm (for certain areas)[11]	—	
	Annual Arithmetic Mean	—		0.030 ppm (for certain areas)[11]	—	
Lead[12,13]	30 Day Average	1.5 µg/m^3	Atomic Absorption	—	—	High Volume Sampler and Atomic Absorption
	Calendar Quarter	—		1.5 µg/m^3 (for certain areas)[12]	Same as Primary Standard	
	Rolling 3-Month Average	—		0.15 µg/m^3		
Visibility Reducing Particles[14]	8 Hour	See footnote 14	Beta Attenuation and Transmittance through Filter Tape	**No National Standards**		
Sulfates	24 Hour	25 µg/m^3	Ion Chromatography			
Hydrogen Sulfide	1 Hour	0.03 ppm (42 µg/m^3)	Ultraviolet Fluorescence			
Vinyl Chloride[12]	24 Hour	0.01 ppm (26 µg/m^3)	Gas Chromatography			

See footnotes on next page …

For more information please call ARB-PIO at (916) 322-2990 **California Air Resources Board (5/4/16)**

TABLE 2-2: AMBIENT AIR QUALITY STANDARDS (2 OF 2)

1. California standards for ozone, carbon monoxide (except 8-hour Lake Tahoe), sulfur dioxide (1 and 24 hour), nitrogen dioxide, and particulate matter (PM10, PM2.5, and visibility reducing particles), are values that are not to be exceeded. All others are not to be equaled or exceeded. California ambient air quality standards are listed in the Table of Standards in Section 70200 of Title 17 of the California Code of Regulations.
2. National standards (other than ozone, particulate matter, and those based on annual arithmetic mean) are not to be exceeded more than once a year. The ozone standard is attained when the fourth highest 8-hour concentration measured at each site in a year, averaged over three years, is equal to or less than the standard. For PM10, the 24 hour standard is attained when the expected number of days per calendar year with a 24-hour average concentration above 150 $\mu g/m^3$ is equal to or less than one. For PM2.5, the 24 hour standard is attained when 98 percent of the daily concentrations, averaged over three years, are equal to or less than the standard. Contact the U.S. EPA for further clarification and current national policies.
3. Concentration expressed first in units in which it was promulgated. Equivalent units given in parentheses are based upon a reference temperature of 25°C and a reference pressure of 760 torr. Most measurements of air quality are to be corrected to a reference temperature of 25°C and a reference pressure of 760 torr; ppm in this table refers to ppm by volume, or micromoles of pollutant per mole of gas.
4. Any equivalent measurement method which can be shown to the satisfaction of the ARB to give equivalent results at or near the level of the air quality standard may be used.
5. National Primary Standards: The levels of air quality necessary, with an adequate margin of safety to protect the public health.
6. National Secondary Standards: The levels of air quality necessary to protect the public welfare from any known or anticipated adverse effects of a pollutant.
7. Reference method as described by the U.S. EPA. An "equivalent method" of measurement may be used but must have a "consistent relationship to the reference method" and must be approved by the U.S. EPA.
8. On October 1, 2015, the national 8-hour ozone primary and secondary standards were lowered from 0.075 to 0.070 ppm.
9. On December 14, 2012, the national annual PM2.5 primary standard was lowered from 15 $\mu g/m^3$ to 12.0 $\mu g/m^3$. The existing national 24-hour PM2.5 standards (primary and secondary) were retained at 35 $\mu g/m^3$, as was the annual secondary standard of 15 $\mu g/m^3$. The existing 24-hour PM10 standards (primary and secondary) of 150 $\mu g/m^3$ also were retained. The form of the annual primary and secondary standards is the annual mean, averaged over 3 years.
10. To attain the 1-hour national standard, the 3-year average of the annual 98th percentile of the 1-hour daily maximum concentrations at each site must not exceed 100 ppb. Note that the national 1-hour standard is in units of parts per billion (ppb). California standards are in units of parts per million (ppm). To directly compare the national 1-hour standard to the California standards the units can be converted from ppb to ppm. In this case, the national standard of 100 ppb is identical to 0.100 ppm.
11. On June 2, 2010, a new 1-hour SO_2 standard was established and the existing 24-hour and annual primary standards were revoked. To attain the 1-hour national standard, the 3-year average of the annual 99th percentile of the 1-hour daily maximum concentrations at each site must not exceed 75 ppb. The 1971 SO_2 national standards (24-hour and annual) remain in effect until one year after an area is designated for the 2010 standard, except that in areas designated nonattainment for the 1971 standards, the 1971 standards remain in effect until implementation plans to attain or maintain the 2010 standards are approved.

    Note that the 1-hour national standard is in units of parts per billion (ppb). California standards are in units of parts per million (ppm). To directly compare the 1-hour national standard to the California standard the units can be converted to ppm. In this case, the national standard of 75 ppb is identical to 0.075 ppm.
12. The ARB has identified lead and vinyl chloride as 'toxic air contaminants' with no threshold level of exposure for adverse health effects determined. These actions allow for the implementation of control measures at levels below the ambient concentrations specified for these pollutants.
13. The national standard for lead was revised on October 15, 2008 to a rolling 3-month average. The 1978 lead standard (1.5 $\mu g/m^3$ as a quarterly average) remains in effect until one year after an area is designated for the 2008 standard, except that in areas designated nonattainment for the 1978 standard, the 1978 standard remains in effect until implementation plans to attain or maintain the 2008 standard are approved.
14. In 1989, the ARB converted both the general statewide 10-mile visibility standard and the Lake Tahoe 30-mile visibility standard to instrumental equivalents, which are "extinction of 0.23 per kilometer" and "extinction of 0.07 per kilometer" for the statewide and Lake Tahoe Air Basin standards, respectively.

For more information please call ARB-PIO at (916) 322-2990 **California Air Resources Board (5/4/16)**

2.6 REGIONAL AIR QUALITY

Air pollution contributes to a wide variety of adverse health effects. The EPA has established NAAQS for six of the most common air pollutants: CO, Pb, O_3, particulate matter (PM_{10} and $PM_{2.5}$), NO_2, and SO_2 which are known as criteria pollutants. The SCAQMD monitors levels of various criteria pollutants at 37 permanent monitoring stations and 5 single-pollutant source Pb air monitoring sites throughout the air district (7). On December 28, 2021, CARB posted the proposed 2021 amendments to the state and national area designations. See Table 2-3 for attainment designations for the SCAB (8). Appendix 2.1 provides geographic representation of the state and federal attainment status for applicable criteria pollutants within the SCAB.

TABLE 2-3: ATTAINMENT STATUS OF CRITERIA POLLUTANTS IN THE SCAB

Criteria Pollutant	State Designation	Federal Designation
O_3 – 1-hour standard	Nonattainment	--
O_3 – 8-hour standard	Nonattainment	Nonattainment
PM_{10}	Nonattainment	Attainment
$PM_{2.5}$	Nonattainment	Nonattainment
CO	Attainment	Unclassifiable/Attainment
NO_2	Attainment	Unclassifiable/Attainment
SO_2	Attainment	Unclassifiable/Attainment
Pb[1]	Attainment	Unclassifiable/Attainment

Note: See Appendix 2.1 for a detailed map of State/National Area Designations within the SCAB
"-" = The national 1-hour O_3 standard was revoked effective June 15, 2005

2.7 LOCAL AIR QUALITY

The Project site is located within Source Receptor Area (SRA) 38 (9). Within SRA 38, the SCAQMD East San Bernardino Mountains monitoring station, located 0.28 mile north of the Project site, is the nearest long-term air quality monitoring station for $PM_{2.5}$. As the East San Bernardino Mountains monitoring station does not provide data for O3, CO, NO_2, or PM_{10}, the next nearest monitoring stations will be utilized. Data for O_3 and PM_{10} was obtained from the Central San Bernardino Mountains monitoring station, located in SRA 37, approximately 22.31 miles west of the Project site. The nearest station for CO and NO_2 data was obtained from the Central San Bernardino Valley 2 monitoring station which is located approximately 24.18 miles southwest of the Project site in SRA 34. It should be noted that the Central San Bernardino Mountains and Central San Bernardino Valley 2 monitoring stations were utilized in lieu of the East San Bernardino Mountains monitoring station only in instances where data was not available.

The most recent three (3) years of data available is shown on Table 2-4 and is considered to be representative of the local air quality at the Project site (10). Please note, data for SO_2 has been

[1] The Federal nonattainment designation for lead is only applicable towards the Los Angeles County portion of the SCAB.

omitted as attainment is regularly met in the SCAB and few monitoring stations measure SO_2 concentrations.

TABLE 2-4: PROJECT AREA AIR QUALITY MONITORING SUMMARY 2019-2021

Pollutant	Standard	Year		
		2019	2020	2021
O_3				
Maximum Federal 1-Hour Concentration (ppm)		0.137	0.173	0.145
Maximum Federal 8-Hour Concentration (ppm)		0.117	0.136	0.119
Number of Days Exceeding State 1-Hour Standard	> 0.09 ppm	73	104	74
Number of Days Exceeding Federal/State 8-Hour Standard	> 0.070 ppm	109	141	118
CO				
Maximum Federal 1-Hour Concentration	> 35 ppm	1.3	1.9	2.0
Maximum Federal 8-Hour Concentration	> 20 ppm	1.1	1.4	1.6
NO_2				
Maximum Federal 1-Hour Concentration	> 0.100 ppm	0.059	0.054	0.056
Annual Federal Standard Design Value		0.014	0.015	0.015
PM_{10}				
Maximum Federal 24-Hour Concentration (µg/m^3)	> 150 µg/m^3	44	57	44
Annual Federal Arithmetic Mean (µg/m^3)		21.2	23.4	23.2
Number of Days Exceeding Federal 24-Hour Standard	> 150 µg/m^3	0	0	0
Number of Days Exceeding State 24-Hour Standard	> 50 µg/m^3	0	1	0
$PM_{2.5}$				
Maximum Federal 24-Hour Concentration (µg/m^3)	> 35 µg/m^3	31.0	24.3	24.5
Annual Federal Arithmetic Mean (µg/m^3)	> 12 µg/m^3	5.94	7.62	7.04
Number of Days Exceeding Federal 24-Hour Standard	> 35 µg/m^3	0	0	0

ppm = Parts Per Million
Source: Data for O_3, CO, NO_2, PM_{10}, and $PM_{2.5}$ was obtained from SCAQMD Air Quality Data Tables.

2.8 REGULATORY BACKGROUND

2.8.1 FEDERAL REGULATIONS

The EPA is responsible for setting and enforcing the NAAQS for O_3, CO, NO_X, SO_2, PM_{10}, and Pb (11). The EPA has jurisdiction over emissions sources that are under the authority of the federal government including aircraft, locomotives, and emissions sources outside state waters (Outer Continental Shelf). The EPA also establishes emission standards for vehicles sold in states other than California. Automobiles sold in California must meet the stricter emission requirements of the CARB.

The Federal Clean Air Act (CAA) was first enacted in 1955 and has been amended numerous times in subsequent years (1963, 1965, 1967, 1970, 1977, and 1990). The CAA establishes the federal

air quality standards, the NAAQS, and specifies future dates for achieving compliance (12). The CAA also mandates that states submit and implement SIPs for local areas not meeting these standards. These plans must include pollution control measures that demonstrate how the standards will be met.

The 1990 amendments to the CAA that identify specific emission reduction goals for areas not meeting the NAAQS require a demonstration of reasonable further progress toward attainment and incorporate additional sanctions for failure to attain or to meet interim milestones. The sections of the CAA most directly applicable to the development of the Project site include Title I (Non-Attainment Provisions) and Title II (Mobile Source Provisions) (13) (14). Title I provisions were established with the goal of attaining the NAAQS for the following criteria pollutants O_3, NO_2, SO_2, PM_{10}, CO, $PM_{2.5}$, and Pb. The NAAQS were amended in July 1997 to include an additional standard for O_3 and to adopt a NAAQS for $PM_{2.5}$. Table 2-3 (previously presented) provides the NAAQS within the SCAB.

Mobile source emissions are regulated in accordance with Title II provisions. These provisions require the use of cleaner burning gasoline and other cleaner burning fuels such as methanol and natural gas. Automobile manufacturers are also required to reduce tailpipe emissions of hydrocarbons and NO_X. NO_X is a collective term that includes all forms of NO_X which are emitted as byproducts of the combustion process.

2.8.2 CALIFORNIA REGULATIONS

CARB

The CARB, which became part of the CalEPA in 1991, is responsible for ensuring implementation of the California Clean Air Act (AB 2595), responding to the federal CAA, and for regulating emissions from consumer products and motor vehicles. AB 2595 mandates achievement of the maximum degree of emissions reductions possible from vehicular and other mobile sources in order to attain the state ambient air quality standards by the earliest practical date. The CARB established the CAAQS for all pollutants for which the federal government has NAAQS and, in addition, establishes standards for SO_4, visibility, hydrogen sulfide (H_2S), and vinyl chloride (C_2H_3Cl). However, at this time, H_2S and C_2H_3Cl are not measured at any monitoring stations in the SCAB because they are not considered to be a regional air quality problem. Generally, the CAAQS are more stringent than the NAAQS (15) (11).

Local air quality management districts, such as the SCAQMD, regulate air emissions from stationary sources such as commercial and industrial facilities. All air pollution control districts have been formally designated as attainment or non-attainment for each CAAQS.

Serious non-attainment areas are required to prepare Air Quality Management Plans (AQMP) that include specified emission reduction strategies in an effort to meet clean air goals. These plans are required to include:

- Application of Best Available Retrofit Control Technology to existing sources;
- Developing control programs for area sources (e.g., architectural coatings and solvents) and indirect sources (e.g. motor vehicle use generated by residential and commercial development);

- A District permitting system designed to allow no net increase in emissions from any new or modified permitted sources of emissions;
- Implementing reasonably available transportation control measures and assuring a substantial reduction in growth rate of vehicle trips and miles traveled;
- Significant use of low emissions vehicles by fleet operators;
- Sufficient control strategies to achieve a 5% or more annual reduction in emissions or 15% or more in a period of three years for ROGs, NO_X, CO and PM_{10}. However, air basins may use alternative emission reduction strategy that achieves a reduction of less than 5% per year under certain circumstances.

TITLE 24 ENERGY EFFICIENCY STANDARDS AND CALIFORNIA GREEN BUILDING STANDARDS

California Code of Regulations (CCR) Title 24 Part 6: The California Energy Code was first adopted in 1978 in response to a legislative mandate to reduce California's energy consumption.

The standards are updated periodically to allow consideration and possible incorporation of new energy efficient technologies and methods. CCR, Title 24, Part 11: California Green Building Standards Code (CALGreen) is a comprehensive and uniform regulatory code for all residential, commercial, and school buildings that went in effect on August 1, 2009, and is administered by the California Building Standards Commission.

CALGreen is updated on a regular basis, with the most recent approved update consisting of the 2022 California Green Building Code Standards that became effective on January 1, 2023. The CEC anticipates that the 2022 energy code will provide $1.5 billion in consumer benefits and reduce GHG emissions by 10 million metric tons (16). The Project would be required to comply with the applicable standards in place at the time plan check submittals are made. These require, among other items (17):

NONRESIDENTIAL MANDATORY MEASURES

- Short-term bicycle parking. If the new project or an additional alteration is anticipated to generate visitor traffic, provide permanently anchored bicycle racks within 200 feet of the visitors' entrance, readily visible to passers-by, for 5% of new visitor motorized vehicle parking spaces being added, with a minimum of one two-bike capacity rack (5.106.4.1.1).
- Long-term bicycle parking. For new buildings with tenant spaces that have 10 or more tenant-occupants, provide secure bicycle parking for 5% of the tenant-occupant vehicular parking spaces with a minimum of one bicycle parking facility (5.106.4.1.2).
- Designated parking for clean air vehicles. In new projects or additions to alterations that add 10 or more vehicular parking spaces, provide designated parking for any combination of low-emitting, fuel-efficient and carpool/van pool vehicles as shown in Table 5.106.5.2 (5.106.5.2).
- EV charging stations. New construction shall facilitate the future installation of EV supply equipment. The compliance requires empty raceways for future conduit and documentation that the electrical system has adequate capacity for the future load. The number of spaces to be provided for is contained in Table 5.106. 5.3.3 (5.106.5.3). Additionally, Table 5.106.5.4.1 specifies requirements for the installation of raceway conduit and panel power requirements for medium- and heavy-duty EV supply equipment for warehouses, grocery stores, and retail stores.

- Outdoor light pollution reduction. Outdoor lighting systems shall be designed to meet the backlight, uplight and glare ratings per Table 5.106.8 (5.106.8).
- Construction waste management. Recycle and/or salvage for reuse a minimum of 65% of the nonhazardous construction and demolition waste in accordance with Section 5.408.1.1. 5.405.1.2, or 5.408.1.3; or meet a local construction and demolition waste management ordinance, whichever is more stringent (5.408.1).
- Excavated soil and land clearing debris. 100% of trees, stumps, rocks and associated vegetation and soils resulting primarily from land clearing shall be reuse or recycled. For a phased project, such material may be stockpiled on site until the storage site is developed (5.408.3).
- Recycling by Occupants. Provide readily accessible areas that serve the entire building and are identified for the depositing, storage, and collection of non-hazardous materials for recycling, including (at a minimum) paper, corrugated cardboard, glass, plastics, organic waste, and metals or meet a lawfully enacted local recycling ordinance, if more restrictive (5.410.1).
- Water conserving plumbing fixtures and fittings. Plumbing fixtures (water closets and urinals) and fittings (faucets and showerheads) shall comply with the following:
    - Water Closets. The effective flush volume of all water closets shall not exceed 1.28 gallons per flush (5.303.3.1)
    - Urinals. The effective flush volume of wall-mounted urinals shall not exceed 0.125 gallons per flush (5.303.3.2.1). The effective flush volume of floor- mounted or other urinals shall not exceed 0.5 gallons per flush (5.303.3.2.2).
    - Showerheads. Single showerheads shall have a minimum flow rate of not more than 1.8 gallons per minute and 80 psi (5.303.3.3.1). When a shower is served by more than one showerhead, the combine flow rate of all showerheads and/or other shower outlets controlled by a single valve shall not exceed 1.8 gallons per minute at 80 psi (5.303.3.3.2).
    - Faucets and fountains. Nonresidential lavatory faucets shall have a maximum flow rate of not more than 0.5 gallons per minute at 60 psi (5.303.3.4.1). Kitchen faucets shall have a maximum flow rate of not more than 1.8 gallons per minute of 60 psi (5.303.3.4.2). Wash fountains shall have a maximum flow rate of not more than 1.8 gallons per minute (5.303.3.4.3). Metering faucets shall not deliver more than 0.20 gallons per cycle (5.303.3.4.4). Metering faucets for wash fountains shall have a maximum flow rate not more than 0.20 gallons per cycle (5.303.3.4.5).
- Outdoor potable water uses in landscaped areas. Nonresidential developments shall comply with a local water efficient landscape ordinance or the current California Department of Water Resources' Model Water Efficient Landscape Ordinance (MWELO), whichever is more stringent (5.304.1).
- Water meters. Separate submeters or metering devices shall be installed for new buildings or additions in excess of 50,000 sf or for excess consumption where any tenant within a new building or within an addition that is project to consume more than 1,000 gallons per day (GPD) (5.303.1.1 and 5.303.1.2).
- Outdoor water uses in rehabilitated landscape projects equal or greater than 2,500 sf. Rehabilitated landscape projects with an aggregate landscape area equal to or greater than 2,500 sf requiring a building or landscape permit (5.304.3).

- Commissioning. For new buildings 10,000 sf and over, building commissioning shall be included in the design and construction processes of the building project to verify that the building systems and components meet the owner's or owner representative's project requirements (5.410.2).

2.8.3 AIR QUALITY MANAGEMENT PLANNING

Currently, the NAAQS and CAAQS are exceeded in most parts of the SCAB. In response, the SCAQMD has adopted a series of AQMPs to meet the state and federal ambient air quality standards (18). AQMPs are updated regularly in order to more effectively reduce emissions, accommodate growth, and to minimize any negative fiscal impacts of air pollution control on the economy. Under State law, the SCAQMD is required to prepare a plan for air quality improvement for pollutants for which the district is in non-compliance. Each iteration of the SCAQMD's Air Quality Management Plan (AQMP) is an update of the previous plan and has a 20-year horizon. The latest AQMP, the 2022 AQMP, adopted by the SCAQMD Governing Board on December 2, 2022. The 2022 AQMP was developed to address the requirements for meeting the 2015 8-hour O_3 standard. The 2022 AQMP builds upon measures already in place from previous AQMPs. It also includes a variety of additional strategies such as regulation, accelerated deployment of available cleaner technologies (e.g., zero emissions technologies, when cost-effective and feasible, and low NO_X technologies in other applications), best management practices, co-benefits from existing programs (e.g., climate and energy efficiency), incentives, and other FCAA measures to achieve the 2015 8-hour ozone standard. The 2022 AQMP incorporates the latest scientific and technological information and planning assumptions, including the 2020-2045 Regional Transportation Plan/Sustainable Communities Strategy (RTP/SCS) and updated emission inventory methodologies for various source categories. The 2022 AQMP requires CARB's adoption before submittal for the U.S. EPA's final approval, which is expected to occur sometime in 2023. Additional discussion and Project consistency with the AQMP is provided in Section 3. 10.

3 PROJECT AIR QUALITY IMPACT

3.1 INTRODUCTION

This study quantifies air quality emissions generated by construction and operation of the Project and addresses whether the Project conflicts with implementation of the SCAQMD's AQMP and Lead Agency planning regulations. The analysis of Project-generated air emissions determines whether the Project would result in a cumulatively considerable net increase of any criteria pollutant for which the SCAB is in non-attainment under an applicable NAAQS and CAAQS. Additionally, the Project has been evaluated to determine whether the Project would expose sensitive receptors to substantial pollutant concentrations and the impacts of odors. The significance of these potential impacts is described in the following sections.

3.2 STANDARDS OF SIGNIFICANCE

The criteria used to determine the significance of potential Project-related air quality impacts are taken from the Initial Study Checklist in Appendix G of the State CEQA Guidelines (14 CCR §§15000, et seq.). Based on these thresholds, a project would result in a significant impact related to air quality if it would (1):

- Conflict with or obstruct implementation of the applicable air quality plan.
- Result in a cumulatively considerable net increase of any criteria pollutant for which the project region is in non-attainment under an applicable federal or state ambient air quality standard.
- Expose sensitive receptors to substantial pollutant concentrations.
- Result in other emissions (such as those leading to odors) adversely affecting a substantial number of people.

The SCAQMD has also developed regional significance thresholds for other regulated pollutants, as summarized at Table 3-1 (19). The SCAQMD's CEQA Air Quality Significance Thresholds (March 2023) indicate that any projects in the SCAB with daily emissions that exceed any of the indicated thresholds should be considered as having an individually and cumulatively significant air quality impact.

TABLE 3-1: MAXIMUM DAILY REGIONAL EMISSIONS THRESHOLDS

Pollutant	Construction Regional Thresholds	Operational Regional Thresholds
NO_X	100 lbs/day	55 lbs/day
VOC	75 lbs/day	55 lbs/day
PM_{10}	150 lbs/day	150 lbs/day
$PM_{2.5}$	55 lbs/day	55 lbs/day
SO_X	150 lbs/day	150 lbs/day
CO	550 lbs/day	550 lbs/day

lbs/day = Pounds Per Day

3.3 CALIFORNIA EMISSIONS ESTIMATOR MODEL™ EMPLOYED TO ANALYZE AIR QUALITY

Land uses such as the Project affect air quality through construction-source and operational-source emissions.

In May 2023 the California Air Pollution Control Officers Association (CAPCOA) in conjunction with other California air districts, including SCAQMD, released the latest version of CalEEMod version 2022.1.1.12. The purpose of this model is to calculate construction-source and operational-source criteria pollutant (VOCs, NO_X, SO_X, CO, PM_{10}, and $PM_{2.5}$) and GHG emissions from direct and indirect sources; and quantify applicable air quality and GHG reductions achieved from mitigation measures (20). Accordingly, the latest version of CalEEMod has been used for this Project to determine construction and operational air quality emissions. Output from the model runs for both construction and operational activity are provided in Appendices 3.1 through 3.5.

3.4 REGIONAL CONSTRUCTION EMISSIONS

As previously stated, the Project consists of the construction and operation of the following facilities:

REPLENISH BIG BEAR COMPONENT 1: BBARWA WWTP UPGRADES

This Replenish Big Bear Component includes upgrades to the BBARWA WWTP, to include 2.2 MGD of full advanced treatment, producing up to 2,210 AFY of purified water. The upgrades include the construction of a 40,000 SF building which would provide the following upgrades and new construction in order of process flow:

- Upgrades to the Oxidation Ditches
- New Denitrification Filter
- New UF and RO filtration membranes
- New UV Disinfection
- New AOP
- New Pellet Reactor: 0.22 MGD

The BBARWA WWTP Treatment Upgrades also includes the installation of about 1,350 LF of brine pipeline anticipated to be sized between 8” to 10” from the pellet reactor to the solar evaporation ponds.

Additionally, the BBARWA WWTP Treatment Upgrades also includes installation of a 50 gpm brine pump station and a 1,520 gpm pump station at the BBARWA WWTP to pump purified water to Shay Pond and Stanfield Marsh.

REPLENISH BIG BEAR COMPONENT 2: LAKE DISCHARGE PIPELINE ALIGNMENT

The Replenish Big Bear Program would ultimately install a pipeline utilizing one of three alignments from the WWTP to Stanfield Marsh in the amount of about 19,940 LF sized at 12” in diameter.

REPLENISH BIG BEAR COMPONENT 3: SHAY POND CONVEYANCE PIPELINE

The Replenish Big Bear Program would ultimately install about 710 LF of 4" pipeline to reach Shay Pond from either an existing pipeline or a new 6" pipeline that would be 5,600 LF. As such, this Replenish Big Bear Component includes the installation of up to 6,310 LF of conveyance pipeline.

REPLENISH BIG BEAR COMPONENT 4: EVAPORATION POND

The Replenish Big Bear Program would include between 23 and 57 acres of evaporation ponds at the BBARWA WWTP site. The ponds would be segmented into different storage basins to allow for evaporation of the brine stream in a cycle of filling with brine, allowing the brine to evaporate, and then removing remaining brine. This Replenish Big Bear Component includes the installation of up to 2 monitoring wells.

REPLENISH BIG BEAR COMPONENT 5: SAND CANYON

The Sand Canyon groundwater recharge project involves extracting Project water stored in the Lake to a temporary storage pond using existing infrastructure owned by a local resort. The Project water will then be pumped and conveyed to the Sand Canyon recharge area using a new pump station and pipeline.

As part of the Replenish Big Bear Program, the following will be constructed:

- A new 471 gpm pump station near the snowmaking pond, at the BBLDWP Sand Canyon Well site, to convey water to Sand Canyon.
- A new 8-inch pipeline that will discharge into Sand Canyon and will be approximately 7,200 feet in length.
- Two monitoring wells for groundwater recharge at Sand Canyon, as required by the future discharge permit.
- Installation of erosion control using rip rap or similar erosion control methods, at Sand Canyon

Because few details are known at this time regarding construction of specific projects, it is assumed that construction of any Project facilities may occur simultaneously. As a conservative measure, and in order to identify the maximum daily emissions, this AQIA assumes that the Project would construct the following features simultaneously:

REPLENISH BIG BEAR COMPONENT 1: BBARWA WWTP UPGRADES

- 2 pump stations: 20 gpm and 1,520 gpm
- 1,350 LF of brine pipeline
- Total building area: 40,000 SF total on site
- Installation of 2 MW on existing BBARWA property

REPLENISH BIG BEAR COMPONENT 2 : LAKE DISCHARGE PIPELINE ALIGNMENT

- 19,940 LF of pipeline

REPLENISH BIG BEAR COMPONENT 3: SHAY POND CONVEYANCE PIPELINE

- 6,310 LF of pipeline on unpaved area

REPLENISH BIG BEAR COMPONENT 4: EVAPORATION POND

- 57 acres of evaporation ponds
- 2 monitoring wells

REPLENISH BIG BEAR COMPONENT 5: SAND CANYON

- 1 pump station
- 2 monitoring wells
- 7,210 LF of conveyance pipeline
- Erosion control/rip rap at pipeline discharge

3.4.1 CONSTRUCTION ACTIVITIES

During construction activities associated with individual projects, emissions of VOCs, NO_X, SO_X, CO, PM_{10}, and $PM_{2.5}$ will likely be released through the burning of fossil fuel in construction equipment, grading fugitive dust, asphalt paving, and the application of architectural coatings during painting activity.

DEMOLITION

The site is currently developed with existing uses/structures and asphalt which would require demolition. Per BBARWA and the Project Team provided data, is anticipated that the following tons of demolished material would be hauled off-site. The cubic yards of export will be analyzed using the BBARWA and the Project Team provided hauling trip length of 100 miles.

Replenish Big Bear Component 1: BBARWA WWTP Upgrades, 3,000 tons of asphalt/concrete would be demolished. Additionally, up to 1,350 CY of asphalt export would be needed.

Replenish Big Bear Component 2: Lake Discharge Pipeline Alignment, it is estimated that up to 5,875 tons of asphalt/concrete would be demolished.

Replenish Big Bear Component 3: Shay Pond Conveyance Pipeline, it was estimated that up to 710 CY of asphalt/concrete export would be needed.

Replenish Big Bear Component 5: Sand Canyon, it was estimated that up to 1,500 tons of asphalt/concrete would be demolished.

GRADING ACTIVITIES

Dust is typically a major concern during grading activities. Because such emissions are not amenable to collection and discharge through a controlled source, they are called “fugitive emissions”. Fugitive dust emissions rates vary as a function of many parameters (soil silt, soil moisture, wind speed, area disturbed, number of vehicles, depth of disturbance or excavation, etc.). The CalEEMod model was utilized to calculate fugitive dust emissions resulting from this phase of activity. The Project is anticipated to include soil import and export within the Project

site boundaries as a part of Project construction. Per BBARWA and the Project Team provided data, it is anticipated that the following cubic yards of export would occur. The cubic yards of export will be analyzed using BBARWA and the Project Team provided hauling trip length of 100 miles.

Replenish Big Bear Component 1: BBARWA WWTP Upgrades, it was estimated that up to 8,000 CY of export would be needed during construction of the building.

Replenish Big Bear Component 4: Evaporation Ponds, it was estimated that up to 175,000 CY of material would be hauled off-site during excavation.

Additionally, for purposes of analysis, and as a conservative measure, it is anticipated that the following cubic yards of export would occur during the pipeline installations. The cubic yards of export will be analyzed using BBARWA and the Project Team provided hauling trip length of 100 miles.

Replenish Big Bear Component 1: BBARWA WWTP Upgrades, it was estimated that up to 1,350 CY of export would be needed.

Replenish Big Bear Component 2: Lake Discharge Pipeline Alignment, it was estimated that up to 19,940 CY of export would be needed.

Replenish Big Bear Component 3: Shay Pond Conveyance Pipeline, it was estimated that up to 6,310 CY of export would be needed.

Replenish Big Bear Component 5: Sand Canyon, it was estimated that up to 7,210 CY of export would be needed.

CONSTRUCTION WORKER VEHICLE TRIPS

Construction emissions for construction worker vehicles traveling to and from the Project site, as well as vendor trips (construction materials delivered to the Project site) were estimated based on information from CalEEMod model defaults, BBARWA and the Project Team. Additionally, it should be noted that the trip lengths were adjusted using BBARWA and the Project Team provided trip length of 100 miles.

3.4.2 CONSTRUCTION DURATION

Based on information provided by BBARWA and the Project Team, construction activities for Replenish Big Bear Component 1 is expected to occur over a 24-month period while construction activities for Project Categories 2 through 5 will occur over a 17-month period. Construction duration utilized in the analysis represents a “worst-case” analysis scenario should construction occur any time after the respective dates since emission factors for construction decrease as the analysis year increases.

TABLE 3-2: CONSTRUCTION DURATION

Construction Activity	Start Date	End Date	Days
Replenish Big Bear Component 1: BBARWA WWTP Upgrades	Jan 2025	Jan 2027	515
Replenish Big Bear Component 2: Lake Discharge Pipeline Alignment	May 2025	Oct 2026	370
Replenish Big Bear Component 3: Shay Pond Conveyance Pipeline	May 2025	Oct 2026	370
Replenish Big Bear Component 4: Evaporation Pond	May 2025	Oct 2026	370
Replenish Big Bear Component 5: Sand Canyon	May 2025	Oct 2026	370

3.4.3 CONSTRUCTION EQUIPMENT

Associated equipment was based on information provided by the Project Description. Please refer to specific detailed modeling inputs/outputs contained in Appendices 3.1 through 3.5 of this AQIA. A detailed summary of construction equipment is provided on Table 3-3.

TABLE 3-3: CONSTRUCTION EQUIPMENT ASSUMPTIONS

Equipment	CalEEMod Equivalent	Amount	Hours Per Day

Source: Construction equipment based on information provided by BBARWA and the Project Team. It should be noted that the Haul/Dump/Delivery trucks are modeled into the Trips & VMT section of CalEEMod.

It is assumed that the construction of analyzed features would use the equipment listed in Table 3-3 simultaneously. Furthermore, the construction equipment provided in Table 3-3 represent a "worst-case" (i.e. overestimation) of actual construction equipment that may likely be used during construction activities.

3.4.4 REGIONAL CONSTRUCTION EMISSIONS SUMMARY

The estimated maximum daily construction emissions without mitigation are summarized on Table 3-4. Detailed unmitigated construction model outputs are presented in Appendices 3.1 through 3.5. Under the assumed scenarios, emissions resulting from the Project construction would exceed criteria pollutant thresholds established by the SCAQMD for emissions of NO_X.

TABLE 3-4: OVERALL CONSTRUCTION EMISSIONS SUMMARY – WITHOUT MITIGATION

Year	Emissions (lbs/day)					
	VOC	NO_X	CO	SO_X	PM_{10}	$PM_{2.5}$
Summer						
Replenish Big Bear Component 1	3.82	27.47	44.30	0.08	7.30	2.95

IMPACTS WITH MITIGATION

The estimated maximum daily construction emissions with mitigation are summarized on Table 3-5. Detailed mitigated construction model outputs are presented in Appendices 3.6 through 3.10. MM AQ-1 is recommended to reduce the severity of the impacts. After implementation of

MM AQ-1, Project construction-source emissions of NO_X would not exceed the applicable SCAQMD thresholds for any criteria pollutant. Thus, a less than significant impact would occur for Project-related construction-source emissions.

3.5 REGIONAL OPERATIONAL EMISSIONS

Long-term air quality impacts occur from mobile source emission generated from project-related traffic and from stationary source emissions generated from natural gas. The proposed Project primarily involves construction activity. For on-going operations, mobile emissions would be generated by the motor vehicles traveling to and from the Project sites during on-going maintenance. However, the Project would generate a nominal number of traffic trips for periodic maintenance and inspections and would not result in any substantive new long-term emissions sources. Stationary area source emissions are typically generated by the consumption of natural gas for space and water heating devices and the use of consumer products. As this Project involves the construction of monitoring wells, conveyance facilities and ancillary facilities, evaporation ponds, advanced water purification facilities, and associated improvements, heating

and consumer products would not be used. Stationary energy emissions would result from energy consumption associated with the proposed Project. However, the proposed Project may include the use of an emergency diesel generator, allowing the pump station to run on backup power in case of emergency. If a backup generator is installed, the lead agency would be required to obtain the applicable permits from SCAQMD for operation of such equipment. The SCAQMD is responsible for issuing permits for the operation of stationary sources in order to reduce air pollution, and to attain and maintain the national and California ambient air quality standards in the SCAB. The Project would not result in a cumulatively considerable net increase of any criteria pollutant for which the Project region is non-attainment. Backup generators would be used only in emergency situations and for routine testing and maintenance purposes and would not contribute a substantial amount of emissions capable of exceeding SCAQMD thresholds. As shown on Table 3-6, project operations would not exceed SCAQMD thresholds, the project would not violate an air quality standard or contribute to an existing violation. Therefore, project operations would not result in a cumulatively considerable net increase of any criteria pollutant and impacts would be less than significant.

TABLE 3-6: SUMMARY OF PEAK OPERATIONAL EMISSIONS

Source	Emissions (lbs/day)					
	VOC	**NO_X**	**CO**	**SO_X**	**PM_{10}**	**$PM_{2.5}$**

3.6 LOCALIZED SIGNIFICANCE

BACKGROUND ON LST DEVELOPMENT

The analysis makes use of methodology included in the SCAQMD *Final Localized Significance Threshold Methodology* (LST Methodology). The SCAQMD has established that impacts to air

quality are significant if there is a potential to contribute or cause localized exceedances of the federal and/or state ambient air quality standards (NAAQS/CAAQS). Collectively, these are referred to as Localized Significance Thresholds (LSTs).

The SCAQMD established LSTs in response to the SCAQMD Governing Board's Environmental Justice Initiative I-4[2]. LSTs represent the maximum emissions from a project that would not cause or contribute to an exceedance of the most stringent applicable federal or state ambient air quality standard at the nearest residence or sensitive receptor. The SCAQMD states that lead agencies can use the LSTs as another indicator of significance in its air quality impact analyses.

LSTs were developed in response to environmental justice and health concerns raised by the public regarding exposure of individuals to criteria pollutants in local communities. To address the issue of localized significance, the SCAQMD adopted LSTs that show whether a project would cause or contribute to localized air quality impacts and thereby cause or contribute to potential localized adverse health effects. The analysis makes use of methodology included in the *LST Methodology* (21).

APPLICABILITY OF LSTS FOR THE PROJECT

For this Project, the appropriate SRA for the LST analysis is the SCAQMD East San Bernardino Mountains (SRA 38). LSTs apply to CO, NO_2, PM_{10}, and $PM_{2.5}$. The SCAQMD produced look-up tables for projects less than or equal to 5 acres in size.

In order to determine the appropriate methodology for determining localized impacts that could occur as a result of Project-related construction, the following process is undertaken:

- Identify the maximum daily on-site emissions that would occur during construction activity:
    - The maximum daily on-site emissions could be based on information provided by the Project Applicant; or
    - The SCAQMD's *Fact Sheet for Applying CalEEMod to Localized Significance Thresholds* and CalEEMod User's Guide *Appendix A: Calculation Details for CalEEMod* can be used to determine the maximum site acreage that is actively disturbed based on the construction equipment fleet and equipment hours as estimated in CalEEMod (22) (23).
- If the total acreage disturbed is less than or equal to 5 acres per day, then the SCAQMD's screening look-up tables are utilized to determine if a Project has the potential to result in a significant impact. The look-up tables establish a maximum daily emissions threshold in lbs/day that can be compared to CalEEMod outputs.
- If the total acreage disturbed is greater than 5 acres per day, then LST impacts may still be conservatively evaluated using the LST look-up tables for a 5-acre disturbance area. Use of the 5-acre disturbance area thresholds can be used to show that even if the daily emissions from all construction activity were emitted within a 5-acre area, and therefore concentrated over a

[2] The purpose of SCAQMD's Environmental Justice program is to ensure that everyone has the right to equal protection from air pollution and fair access to the decision-making process that works to improve the quality of air within their communities. Further, the SCAQMD defines Environmental Justice as "…equitable environmental policymaking and enforcement to protect the health of all residents, regardless of age, culture, ethnicity, gender, race, socioeconomic status, or geographic location, from the health effects of air pollution."

smaller area which would result in greater site adjacent concentrations, the impacts would still be less than significant if the applicable 5-acre thresholds are utilized.

- The *LST Methodology* presents mass emission rates for each SRA, project sizes of 1, 2, and 5 acres, and nearest receptor distances of 25, 50, 100, 200, and 500 meters. For project sizes between the values given, or with receptors at distances between the given receptors, the methodology uses linear interpolation to determine the thresholds.

EMISSIONS CONSIDERED

Based on SCAQMD's *LST Methodology*, emissions for concern during construction activities are on-site NO_X, CO, $PM_{2.5}$, and PM_{10}. The *LST Methodology* clearly states that "off-site mobile emissions from the Project should not be included in the emissions compared to LSTs (24)." As such, for purposes of the construction LST analysis, only emissions included in the CalEEMod "on-site" emissions outputs were considered.

MAXIMUM DAILY DISTURBED-ACREAGE

Based on information provided, it was assumed that 2 acres would be disturbed per day for all Project Categories. This is conservative as the construction impacts are assessed against a smaller acreage threshold which would represent a more conservative assessment.

RECEPTORS

As previously stated, LSTs represent the maximum emissions from a project that would not cause or contribute to an exceedance of the most stringent applicable NAAQS and CAAQS at the nearest residence or sensitive receptor. Receptor locations are off-site locations where individuals may be exposed to emissions from Project activities.

Some people are especially sensitive to air pollution and are given special consideration when evaluating air quality impacts from projects. These groups of people include children, the elderly, and individuals with pre-existing respiratory or cardiovascular illness. Structures that house these persons or places where they gather are defined as "sensitive receptors". These structures typically include uses such as residences, hotels, and hospitals where an individual can remain for 24 hours. Consistent with the LST Methodology, the nearest land use where an individual could remain for 24 hours to the Project site has been used to determine construction and operational air quality impacts for emissions of PM_{10} and $PM_{2.5}$, since PM_{10} and $PM_{2.5}$ thresholds are based on a 24-hour averaging time.

LSTs apply, even for non-sensitive land uses, consistent with *LST Methodology* and SCAQMD guidance. Per the *LST Methodology*, commercial and industrial facilities are not included in the definition of sensitive receptor because employees and patrons do not typically remain onsite for a full 24 hours but are typically onsite for 8 hours or less. However, *LST Methodology* explicitly states that "*LSTs based on shorter averaging periods, such as the NO_2 and CO LSTs, could also be applied to receptors such as industrial or commercial facilities since it is reasonable to assume that a worker at these sites could be present for periods of one to eight hours* (24)." Therefore, any adjacent land use where an individual could remain for 1 or 8-hours, that is located at a closer distance to the Project site than the receptor used for PM_{10} and $PM_{2.5}$ analysis, must be

considered to determine construction and operational LST air impacts for emissions of NO_2 and CO since these pollutants have an averaging time of 1 and 8-hours.

PROJECT-RELATED RECEPTORS

The SCAQMD recommends that the nearest sensitive receptor be considered when determining the Project's potential to cause an individual and cumulatively significant impact. As a conservative measure it is assumed that the nearest sensitive receptor could potentially be located immediately adjacent to construction activities. It should be noted that the LST Methodology also explicitly states that "It is possible that a project may have receptors closer than 25 meters. Projects with boundaries located closer than 25 meters to the nearest receptor should use the LSTs for receptors located at 25 meters (25)." Consistent with the SCAQMD's LST Methodology, a 25-meter receptor distance is utilized in this analysis and provide for a conservative i.e. "health protective" standard of care.

3.7 LOCALIZED CONSTRUCTION-SOURCE EMISSIONS

3.7.1 LOCALIZED THRESHOLDS FOR CONSTRUCTION ACTIVITY

Since the total acreage disturbed is less than five acres per day for construction activities, the SCAQMD's screening look-up tables are utilized in determining impacts. It should be noted that since the look-up tables identifies thresholds at only 1 acre, 2 acres, and 5 acres, linear regression has been utilized to determine localized significance thresholds. Consistent with SCAQMD guidance, the thresholds presented in Table 3-7 were calculated by interpolating the threshold values for the Project's disturbed acreage.

TABLE 3-7: MAXIMUM DAILY LOCALIZED EMISSIONS THRESHOLDS

Pollutant	Construction Localized Thresholds
All Project Categories	
NO_X	170 lbs/day
CO	1,174 lbs/day
PM_{10}	7 lbs/day
$PM_{2.5}$	5 lbs/day

Source: Localized Thresholds presented in this table are based on the SCAQMD Final Localized Significance Threshold Methodology, July 2008

3.7.2 CONSTRUCTION-SOURCE LOCALIZED EMISSIONS

IMPACTS WITHOUT MITIGATION

Table 3-8 identifies the localized impacts at the nearest receptor location in the vicinity of the Project. Without mitigation, localized construction emissions would exceed the applicable SCAQMD LSTs for emissions of PM_{10} during Replenish Big Bear Component 3. Outputs from the model runs for construction LSTs are provided in Appendix 3.1 through 3.5.

TABLE 3-8: LOCALIZED SIGNIFICANCE SUMMARY OF CONSTRUCTION – WITHOUT MITIGATION

IMPACTS WITH MITIGATION

Table 3-9 identifies mitigated localized impacts at the receptors nearest the Project site. After implementation of mitigation measure (MM AQ-1), construction-source emissions would not exceed the applicable SCAQMD LSTs thresholds and would be less-than-significant. Outputs from the model runs for mitigated localized construction-source emissions are provided in Appendix 3.6 through 3.10.

TABLE 3-9: LOCALIZED SIGNIFICANCE SUMMARY OF CONSTRUCTION – WITH MITIGATION

3.8 LOCALIZED OPERATIONAL-SOURCE EMISSIONS

According to SCAQMD localized significance threshold methodology, LSTs would apply to the operational phase of a proposed project if the project includes stationary sources or attracts mobile sources that may spend extended periods queuing and idling at the site (e.g., warehouse or transfer facilities). As previously discussed, the Project would generate a nominal number of traffic trips in the context of on-going maintenance resulting in a negligible amount of new mobile source emissions. Additionally, all pumps associated with the Project are assumed to be electrically powered and would not directly generate air emissions. However, the proposed Project may include the use of an emergency diesel generators, allowing pump stations to run on backup power in case of emergency. If backup generator would be installed, the lead agency would be required to obtain the applicable permits from SCAQMD for operation of such equipment. The SCAQMD is responsible for issuing permits for the operation of stationary

sources in order to reduce air pollution, and to attain and maintain the national and California ambient air quality standards in the SCAB. Upon compliance with SCAQMD permitting procedures, localized emissions from any potential diesel generator would not result in substantial pollutant concentrations capable of exceeding operational LST thresholds. Therefore, the Project would not expose sensitive receptors to substantial pollutant concentrations and impacts would be less than significant.

3.9 CO "HOT SPOT" ANALYSIS

As discussed below, the Project would not result in potentially adverse CO concentrations or "hot spots." An adverse CO concentration, known as a "hot spot", would occur if an exceedance of the state one-hour standard of 20 ppm or the eight-hour standard of 9 ppm were to occur.

It has long been recognized that CO hotspots are caused by vehicular emissions, primarily when idling at congested intersections. In response, vehicle emissions standards have become increasingly stringent in the last twenty years. Currently, the allowable CO emissions standard in California is a maximum of 3.4 grams/mile for passenger cars (there are requirements for certain vehicles that are more stringent). With the turnover of older vehicles, introduction of cleaner fuels, and implementation of increasingly sophisticated and efficient emissions control technologies, CO concentration in the SCAB is now designated as attainment.

To establish a more accurate record of baseline CO concentrations affecting the SCAB, a CO "hot spot" analysis was conducted in 2003 for four busy intersections in Los Angeles at the peak morning and afternoon time periods[3]. This "hot spot" analysis did not predict any exceedance e of the 1-hour (20.0 ppm) or 8-hour (9.0 ppm) CO standards, as shown on Table 3-10.

TABLE 3-10: CO MODEL RESULTS

Intersection Location	CO Concentrations (ppm)		
	Morning 1-hour	Afternoon 1-hour	8-hour
Wilshire Boulevard/Veteran Avenue	4.6	3.5	3.7
Sunset Boulevard/Highland Avenue	4	4.5	3.5
La Cienega Boulevard/Century Boulevard	3.7	3.1	5.2
Long Beach Boulevard/Imperial Highway	3	3.1	8.4

Source: 2003 AQMP, Appendix V: Modeling and Attainment Demonstrations
Notes: Federal 1-hour standard is 35 ppm and the deferral 8-hour standard is 9.0 ppm.

Based on the SCAQMD's 2003 AQMP and the 1992 Federal Attainment Plan for Carbon Monoxide (*1992 CO Plan*), peak carbon monoxide concentrations in the SCAB were a result of unusual meteorological and topographical conditions and not a result of traffic volumes and congestion at a particular intersection. As evidence of this, for example, of the 8.4 ppm 8-hr CO concentration measured at the Long Beach Blvd. and Imperial Hwy. intersection (i.e., the highest CO generating intersection within the "hot spot" analysis), only 0.7 ppm was attributable to the

[3] The CO "hot spot" analysis conducted in 2003 is the most current study used for CO "hot spot" analysis in the SCAB.

traffic volumes and congestion at this intersection; the remaining 7.7 ppm were due to the ambient air measurements at the time the 2003 AQMP was prepared (26). In contrast, an adverse CO concentration, known as a "hot spot", would occur if an exceedance of the state one-hour standard of 20 parts per million (ppm) or the eight-hour standard of 9 ppm were to occur.

The ambient 1-hr and 8-hr CO concentration within the Project study area is estimated to be 2.0 ppm and 1.6 ppm, respectively (data from East San Bernardino Mountains monitoring station for 2021). Therefore, even if the traffic volumes for the proposed Project were ten times the traffic volumes generated at the Long Beach Blvd. and Imperial Hwy. intersection, due to the on-going improvements in ambient air quality and vehicular emissions controls, the Project would not be capable of resulting in a CO "hot spot" at any study area intersections. As noted above, only 0.7 ppm were attributable to the traffic volumes and congestion at one of the busiest intersections in the SCAB. Therefore if these traffic volumes were multiplied by ten times, it could be expected that the CO attributable to traffic would increase tenfold as well, resulting in 7 ppm – even if this were added to either the 1-hour or 8-hour CO concentrations within the Project study area, this would result in 9.0 ppm and 8.6 ppm for the 1-hr and 8-hr timeframes, respectively. Neither of which would exceed the applicable 1-hr standard of 20 ppm or the 8-hr standard of 9 ppm.

Similar considerations are also employed by other Air Districts when evaluating potential CO concentration impacts. More specifically, the Bay Area Air Quality Management District (BAAQMD) concludes that under existing and future vehicle emission rates, a given project would have to increase traffic volumes at a single intersection by more than 44,000 vehicles per hour (vph)—or 24,000 vph where vertical and/or horizontal air does not mix—in order to generate a significant CO impact (27). Traffic volumes generating the CO concentrations for the "hot spot" analysis is shown on Table 3-11. The busiest intersection evaluated was that at Wilshire Boulevard and Veteran Avenue, which had AM/PM traffic volumes of 8,062 vph and 7,719 vph respectively (26).

At buildout of the Project, the highest daily traffic volumes generated at the roadways within the vicinity of the Project are expected to generate less than the highest daily traffic volumes generated at the busiest intersection in the CO "hot spot" analysis. As such, the Project would not likely exceed the most stringent 1-hour CO standard.

TABLE 3-11: TRAFFIC VOLUMES

Intersection Location	Peak Traffic Volumes (vph)				
	Eastbound (AM/PM)	Westbound (AM/PM)	Southbound (AM/PM)	Northbound (AM/PM)	Total (AM/PM)
Wilshire Boulevard/Veteran Avenue	4,954/2,069	1,830/3,317	721/1,400	560/933	8,062/7,719
Sunset Boulevard/Highland Avenue	1,417/1,764	1,342/1,540	2,304/1,832	1,551/2,238	6,614/5,374
La Cienega Boulevard/Century Boulevard	2,540/2,243	1,890/2,728	1,384/2,029	821/1,674	6,634/8,674

3.10 AIR QUALITY MANAGEMENT PLANNING

The Project site is located within the SCAB, which is characterized by relatively poor air quality. The SCAQMD has jurisdiction over an approximately 10,743 square-mile area consisting of the four-county Basin and the Los Angeles County and Riverside County portions of what use to be referred to as the Southeast Desert Air Basin. In these areas, the SCAQMD is principally responsible for air pollution control, and works directly with the Southern California Association of Governments (SCAG), county transportation commissions, local governments, as well as state and federal agencies to reduce emissions from stationary, mobile, and indirect sources to meet state and federal ambient air quality standards.

Currently, these state and federal air quality standards are exceeded in most parts of the SCAB. In response, the SCAQMD has adopted a series of AQMPs to meet the state and federal ambient air quality standards. AQMPs are updated regularly in order to more effectively reduce emissions, accommodate growth, and to minimize any negative fiscal impacts of air pollution control on the economy.

In December 2022, the SCAQMD released the *Final 2022 AQMP* (*2022 AQMP*). The *2022 AQMP* continues to evaluate current integrated strategies and control measures to meet the CAAQS, as well as explore new and innovative methods to reach its goals. Some of these approaches include utilizing incentive programs, recognizing existing co-benefit programs from other sectors, and developing a strategy with fair-share reductions at the federal, state, and local levels (28). Similar to the 2016 AQMP, the *2022 AQMP* incorporates scientific and technological information and planning assumptions, including the *2020-2045 RTP/SCS*, a planning document that supports the integration of land use and transportation to help the region meet the federal CAA requirements (29). The Project's consistency with the AQMP will be determined using the *2022 AQMP* as discussed below.

Criteria for determining consistency with the AQMP are defined in Chapter 12, Section 12.2 and Section 12.3 of the SCAQMD's CEQA Air Quality Handbook (1993) (30). These indicators are discussed below:

3.10.1 CONSISTENCY CRITERION NO. 1

The proposed Project will not result in an increase in the frequency or severity of existing air quality violations or cause or contribute to new violations or delay the timely attainment of air quality standards or the interim emissions reductions specified in the AQMP.

The violations that Consistency Criterion No. 1 refers to are the CAAQS and NAAQS. CAAQS and NAAQS violations would occur if regional or localized significance thresholds were exceeded.

Construction Impacts – Consistency Criterion 1

The violations that Consistency Criterion No. 1 refers to are the CAAQS and NAAQS. CAAQS and NAAQS violations would occur if localized or regional significance thresholds were exceeded. The Project would not exceed the applicable LST thresholds or regional significance thresholds for

construction activity after implementation of applicable mitigation measures. Therefore, the Project would not conflict with the AQMP according to this criterion.

Operational Impacts – Consistency Criterion 1

As evaluated, the Project's localized and regional operation-source emissions would not exceed applicable regional significance threshold and LST thresholds. As such, a less than significant impact is expected.

On the basis of the preceding discussion, the Project would not conflict with the AQMP according to this criterion.

3.10.2 CONSISTENCY CRITERION NO. 2

The Project will not exceed the assumptions in the AQMP based on the years of Project build-out phase.

The 2022 AQMP demonstrates that the applicable ambient air quality standards can be achieved within the timeframes required under federal law. Growth projections from local general plans adopted by counties in the district are provided to the SCAG, which develops regional growth forecasts, which are then used to develop future air quality forecasts for the AQMP. Development consistent with the growth projections of the Big Bear Area Regional Wastewater Agency is considered to be consistent with the AQMP.

Construction Impacts – Consistency Criterion 2

Peak day emissions generated by construction activities are largely independent of land use assignments, but rather are a function of development scope and maximum area of disturbance. Irrespective of the site's land use designation, development of the site to its maximum potential would likely occur, with disturbance of the entire site occurring during construction activities. As such, when considering that no emissions thresholds will be exceeded, a less than significant impact would result.

Operational Impacts – Consistency Criterion 2

Since the Project's proposed land uses are consistent with the Big Bear Area Regional Wastewater Agency and as the Project's construction and operational-source air pollutant emissions would not exceed the regional or localized significance thresholds, the Project is determined to be consistent with the second criterion.

On the basis of the preceding discussion, the Project is determined to be consistent with the second criterion.

AQMP CONSISTENCY CONCLUSION

The Project would not result in or cause NAAQS or CAAQS violations. The Project proposes to construct but rather involves pump station, well construction, monitoring and associated improvements. The Project is therefore considered to be consistent with the AQMP.

3.11 POTENTIAL IMPACTS TO SENSITIVE RECEPTORS

The potential impact of Project-generated air pollutant emissions at sensitive receptors has also been considered. Sensitive receptors can include uses such as long-term health care facilities, rehabilitation centers, and retirement homes. Residences, schools, playgrounds, childcare centers, and athletic facilities can also be considered as sensitive receptors.

Results of the LST analysis indicate that, the Project would not exceed the SCAQMD localized significance thresholds during construction. Therefore, sensitive receptors would not be exposed to substantial pollutant concentrations during Project construction.

Results of the LST analysis indicate that the Project would not exceed the SCAQMD localized significance thresholds during operational activity. Further Project traffic would not create or result in a CO "hotspot." Therefore, sensitive receptors would not be exposed to substantial pollutant concentrations as the result of Project construction.

3.12 ODORS

The potential for the Project to generate objectionable odors has also been considered. Land uses generally associated with odor complaints include:

- Agricultural uses (livestock and farming)
- Wastewater treatment plants
- Food processing plants
- Chemical plants
- Composting operations
- Refineries
- Landfills
- Dairies
- Fiberglass molding facilities

The Project contains a land use associated with emitting objectionable odors. Potential odor sources associated with the proposed Project may result from construction equipment exhaust during construction activities and the temporary storage of typical solid waste (refuse) associated with the proposed Project's uses. Standard construction requirements would minimize odor impacts from construction. The construction odor emissions would be temporary, short-term, and intermittent in nature and would cease upon completion of the respective phase of construction and is thus considered less than significant.

The Project could potentially emit odors from the evaporation ponds that may result in an odor complaint. However, based on a review of similar solar evaporations pond operations handling brine, odor does not appear to be an issue with operations of this type. BBARWA will maintain the brine evaporation ponds by periodically removing the salt crystals and hauling the precipitated crystal to the local landfill. This is anticipated to prevent odors from accumulating at the solar evaporation ponds and migrating to nearby sensitive receptors. Furthermore, given the

location proposed for installation of the brine evaporation ponds at a 0.25 mile distance from the nearest sensitive receptor (residents, hospitals, senior living, churches, schools, etc.) any odors generated by the brine evaporation ponds are anticipated to dissipate at the nearest sensitive receptor. Furthermore, the operations of the BBARWA WWTP involve a greater potential for odors to travel, and odor nuisance has not been a reported issue in the Community as a result of BBARWA operations. Thus, there has been no indication that odor traveling to sensitive receptors will result from operation of the brine ponds, but mitigation has been identified that would require odor observation for the first year of the Program, with an odor response component in the event that odors are observed by nearby sensitive receptors. Additionally, it is expected that Project-generated refuse would be stored in covered containers and removed at regular intervals in compliance with the lead agency's solid waste regulations. The Project would be required to comply with SCAQMD Rule 402 to prevent occurrences of public nuisances. Therefore, odors associated with the proposed Project construction and operations would be less than significant and no mitigation is required (31).

3.13 CUMULATIVE IMPACTS

As previously shown in Table 2-3, the CAAQS designate the Project site as nonattainment for O_3 PM_{10}, and $PM_{2.5}$ while the NAAQS designates the Project site as nonattainment for O_3 and $PM_{2.5}$.

The AQMD has published a report on how to address cumulative impacts from air pollution: *White Paper on Potential Control Strategies to Address Cumulative Impacts from Air Pollution* (32). In this report the AQMD clearly states (Page D-3):

> *"…the AQMD uses the same significance thresholds for project specific and cumulative impacts for all environmental topics analyzed in an Environmental Assessment or Environmental Impact Report (EIR). The only case where the significance thresholds for project specific and cumulative impacts differ is the Hazard Index (HI) significance threshold for TAC emissions. The project specific (project increment) significance threshold is HI > 1.0 while the cumulative (facility-wide) is HI > 3.0. It should be noted that the HI is only one of three TAC emission significance thresholds considered (when applicable) in a CEQA analysis. The other two are the maximum individual cancer risk (MICR) and the cancer burden, both of which use the same significance thresholds (MICR of 10 in 1 million and cancer burden of 0.5) for project specific and cumulative impacts.*
>
> *Projects that exceed the project-specific significance thresholds are considered by the SCAQMD to be cumulatively considerable. This is the reason project-specific and cumulative significance thresholds are the same. Conversely, projects that do not exceed the project-specific thresholds are generally not considered to be cumulatively significant."*`

Therefore, this analysis assumes that individual projects that do not generate operational or construction emissions that exceed the SCAQMD's recommended daily thresholds for project-specific impacts would also not cause a cumulatively considerable increase in emissions for those

pollutants for which the Basin is in nonattainment, and, therefore, would not be considered to have a significant, adverse air quality impact. Alternatively, individual project-related construction and operational emissions that exceed SCAQMD thresholds for project-specific impacts would be considered cumulatively considerable.

CONSTRUCTION IMPACTS

The Project-specific evaluation of emissions presented in the preceding analysis demonstrates that Project construction-source air pollutant emissions would not result in exceedances of regional thresholds after implementation of MM AQ-1 and MM AQ-2. Therefore, Project construction-source emissions would be considered less than significant on a project-specific and cumulative basis.

OPERATIONAL IMPACTS

The Project-specific evaluation of emissions presented in the preceding analysis demonstrates that proposed Project operation-source air pollutant emissions would not result in exceedances of regional thresholds. Therefore, proposed Project operation-source emissions would be considered less than significant on a project-specific and cumulative basis.

APPENDIX 2.1:

STATE/FEDERAL ATTAINMENT STATUS OF CRITERIA POLLUTANTS

Appendix C
Maps and Tables of Area Designations for State and National Ambient Air Quality Standards

Appendix C
Maps and Tables of Area Designations for State and National Ambient Air Quality Standards

This attachment fulfills the requirement of Health and Safety Code section 40718 for CARB to publish maps that identify areas where one or more violations of any State ambient air quality standard (State standard) or national ambient air quality standard (national standard) have been measured. The national standards are those promulgated under section 109 of the federal Clean Air Act (42 U.S.C. § 7409).

This attachment is divided into three parts. The first part comprises a table showing the levels, averaging times, and measurement methods for each of the State and national standards. This is followed by a section containing maps and tables showing the area designations for each pollutant for which there is a State standard in the California Code of Regulations, title 17, section 70200. The last section contains maps and tables showing the most current area designations for the national standards.

Ambient Air Quality Standards

(Updated 5/4/16)

Pollutant	Averaging Time	California Standards [1]		National Standards [1]		
		Concentration [3]	Method [4]	Primary [5,6]	Secondary [5,6]	Method [7]
Ozone (O_3)[8]	1 Hour	0.09 ppm (180 µg/m³)	Ultraviolet Photometry	—	Same as Primary Standard	Ultraviolet Photometry
	8 Hour	0.070 ppm (137 µg/m³)		0.070 ppm (137 µg/m³)		
Respirable Particulate Matter (PM10)[9]	**24 Hour**	**50 µg/m³**	**Gravimetric or Beta Attenuation**	**150 µg/m³**	**Same as Primary Standard**	**Inertial Separation and Gravimetric Analysis**
	Annual Arithmetic Mean	**20 µg/m³**		—		
Fine Particulate Matter ($PM_{2.5}$)[9]	24 Hour	—	—	35 µg/m³	Same as Primary Standard	Inertial Separation and Gravimetric Analysis
	Annual Arithmetic Mean	12 µg/m³	Gravimetric or Beta Attenuation	12.0 µg/m³	15 µg/m³	
Carbon Monoxide (CO)	**1 Hour**	**20 ppm (23 mg/m³)**	**Non-Dispersive Infrared Photometry (NDIR)**	**35 ppm (40 mg/m³)**	—	**Non-Dispersive Infrared Photometry (NDIR)**
	8 Hour	**9.0 ppm (10 mg/m³)**		**9 ppm (10 mg/m³)**	—	
	8 Hour (Lake Tahoe)	**6 ppm (7 mg/m³)**		—	—	
Nitrogen Dioxide (NO_2)[10]	1 Hour	0.18 ppm (339 µg/m³)	Gas Phase Chemiluminescence	100 ppb (188 µg/m³)	—	Gas Phase Chemiluminescence
	Annual Arithmetic Mean	0.030 ppm (57 µg/m³)		0.053 ppm (100 µg/m³)	Same as Primary Standard	
Sulfur Dioxide (SO_2)[11]	**1 Hour**	**0.25 ppm (655 µg/m³)**	**Ultraviolet Fluorescence**	**75 ppb (196 µg/m³)**	—	**Ultraviolet Fluorescence; Spectrophotometry (Pararosaniline Method)**
	3 Hour	—		—	**0.5 ppm (1300 µg/m³)**	
	24 Hour	**0.04 ppm (105 µg/m³)**		**0.14 ppm (for certain areas)[11]**	—	
	Annual Arithmetic Mean	—		**0.030 ppm (for certain areas)[11]**	—	
Lead[12,13]	30 Day Average	1.5 µg/m³	Atomic Absorption	—	—	High Volume Sampler and Atomic Absorption
	Calendar Quarter	—		1.5 µg/m³ (for certain areas)[12]	Same as Primary Standard	
	Rolling 3-Month Average	—		0.15 µg/m³		
Visibility Reducing Particles[14]	**8 Hour**	**See footnote 14**	**Beta Attenuation and Transmittance through Filter Tape**	**No National Standards**		
Sulfates	24 Hour	25 µg/m³	Ion Chromatography			
Hydrogen Sulfide	**1 Hour**	**0.03 ppm (42 µg/m³)**	**Ultraviolet Fluorescence**			
Vinyl Chloride[12]	24 Hour	0.01 ppm (26 µg/m³)	Gas Chromatography			

See footnotes on next page ...

1. California standards for ozone, carbon monoxide (except 8-hour Lake Tahoe), sulfur dioxide (1- and 24-hour), nitrogen dioxide, and particulate matter (PM10, PM2.5, and visibility reducing particles), are values that are not to be exceeded. All others are not to be equaled or exceeded. California ambient air quality standards are listed in the Table of Standards in Section 70200 of Title 17 of the California Code of Regulations.

2. National standards (other than ozone, particulate matter, and those based on annual arithmetic mean) are not to be exceeded more than once a year. The ozone standard is attained when the fourth highest 8-hour concentration measured at each site in a year, averaged over three years, is equal to or less than the standard. For PM10, the 24-hour standard is attained when the expected number of days per calendar year with a 24-hour average concentration above 150 $\mu g/m^3$ is equal to or less than one. For PM2.5, the 24-hour standard is attained when 98 percent of the daily concentrations, averaged over three years, are equal to or less than the standard. Contact the U.S. Environmental Protection Agency (U.S. EPA) for further clarification and current national policies.

3. Concentration expressed first in units in which it was promulgated. Equivalent units given in parentheses are based upon a reference temperature of 25°C and a reference pressure of 760 torr. Most measurements of air quality are to be corrected to a reference temperature of 25°C and a reference pressure of 760 torr; ppm in this table refers to ppm by volume, or micromoles of pollutant per mole of gas.

4. Any equivalent measurement method which can be shown to the satisfaction of the CARB to give equivalent results at or near the level of the air quality standard may be used.

5. National Primary Standards: The levels of air quality necessary, with an adequate margin of safety to protect the public health.

6. National Secondary Standards: The levels of air quality necessary to protect the public welfare from any known or anticipated adverse effects of a pollutant.

7. Reference method as described by the U.S. EPA. An "equivalent method" of measurement may be used but must have a "consistent relationship to the reference method" and must be approved by the U.S. EPA.

8. On October 1, 2015, the national 8-hour ozone primary and secondary standards were lowered from 0.075 to 0.070 ppm.

9. On December 14, 2012, the national annual PM2.5 primary standard was lowered from 15 $\mu g/m^3$ to 12.0 $\mu g/m^3$. The existing national 24-hour PM2.5 standards (primary and secondary) were retained at 35 $\mu g/m^3$, as was the annual secondary standard of 15 $\mu g/m^3$. The existing 24-hour PM10 standards (primary and secondary) of 150 $\mu g/m^3$ also were retained. The form of the annual primary and secondary standards is the annual mean, averaged over 3 years.

10. To attain the 1-hour national standard, the 3-year average of the annual 98th percentile of the 1-hour daily maximum concentrations at each site must not exceed 100 ppb. Note that the national 1-hour standard is in units of parts per billion (ppb). California standards are in units of parts per million (ppm). To directly compare the national 1-hour standard to the California standards the units can be converted from ppb to ppm. In this case, the national standard of 100 ppb is identical to 0.100 ppm.

11. On June 2, 2010, a new 1-hour SO_2 standard was established and the existing 24-hour and annual primary standards were revoked. To attain the 1-hour national standard, the 3-year average of the annual 99th percentile of the 1-hour daily maximum concentrations at each site must not exceed 75 ppb. The 1971 SO_2 national standards (24-hour and annual) remain in effect until one year after an area is designated for the 2010 standard, except that in areas designated nonattainment for the 1971 standards, the 1971 standards remain in effect until implementation plans to attain or maintain the 2010 standards are approved.

    Note that the 1-hour national standard is in units of parts per billion (ppb). California standards are in units of parts per million (ppm). To directly compare the 1-hour national standard to the California standard the units can be converted to ppm. In this case, the national standard of 75 ppb is identical to 0.075 ppm.

12. The CARB has identified lead and vinyl chloride as 'toxic air contaminants' with no threshold level of exposure for adverse health effects determined. These actions allow for the implementation of control measures at levels below the ambient concentrations specified for these pollutants.

13. The national standard for lead was revised on October 15, 2008 to a rolling 3-month average. The 1978 lead standard (1.5 $\mu g/m^3$)as a quarterly average) remains in effect until one year after an area is designated for the 2008 standard, except that in areas designated nonattainment for the 1978 standard, the 1978 standard remains in effect until implementation plans to attain or maintain the 2008 standard are approved.

14. In 1989, the CARB converted both the general statewide 10-mile visibility standard and the Lake Tahoe 30-mile visibility standard to instrumental equivalents, which are "extinction of 0.23 per kilometer" and "extinction of 0.07 per kilometer" for the statewide and Lake Tahoe Air Basin standards, respectively.

Area Designations for the State Ambient Air Quality Standards

The following maps and tables show the area designations for each pollutant with a State standard set forth in the California Code of Regulations, title 17, section 60200. Each area is identified as attainment, nonattainment, nonattainment-transitional, or unclassified for each pollutant, as shown below:

Attainment	A
Nonattainment	N
Nonattainment-Transitional	NA-T
Unclassified	U

In general, CARB designates areas by air basin for pollutants with a regional impact and by county for pollutants with a more local impact. However, when there are areas within an air basin or county with distinctly different air quality deriving from sources and conditions not affecting the entire air basin or county, CARB may designate a smaller area. Generally, when boundaries of the designated area differ from the air basin or county boundaries, the description of the specific area is referenced at the bottom of the summary table.

[1] AB 3048 (Olberg) and AB 2525 (Miller) signed into law in 1996, made changes to Health and Safety Code, section 40925.5. One of the changes allows nonattainment districts to become nonattainment-transitional for ozone by operation of law.

Area Designations for the National Ambient Air Quality Standards

The following maps and tables show the area designations for each pollutant with a national ambient air quality standard. Additional information about the federal area designations is available on the U.S. Environmental Protection Agency (U.S. EPA) website:

https://www.epa.gov/green-book

Over the last several years, U.S. EPA has been reviewing the levels of the various national standards. The agency has already promulgated new standard levels for some pollutants and is considering revising the levels for others. Information about the status of these reviews is available on the U.S. EPA website:

https://www.epa.gov/criteria-air-pollutants

Designation Categories

Suspended Particulate Matter (PM_{10}). The U.S. EPA uses three categories to designate areas with respect to PM_{10}:

- Attainment (A)
- Nonattainment (N)
- Unclassifiable (U)

Ozone, Fine Suspended Particulate Matter ($PM_{2.5}$), Carbon Monoxide (CO), and Nitrogen Dioxide (NO_2). The U.S. EPA uses two categories to designate areas with respect to these standards:

- Nonattainment (N)
- Unclassifiable/Attainment (U/A)

The national 1-hour ozone standard was revoked effective June 15, 2005, and the area designations map reflects the 2015 national 8-hour ozone standard of 0.070 ppm. Area designations were finalized on August 3, 2018.

On December 14, 2012, the U.S. EPA established a new national annual primary $PM_{2.5}$ standard of 12.0 µg/m^3. Area designations were finalized in December 2014. The current designation map reflects the most recently revised (2012) annual average standard of 12.0 µg/m^3 as well as the 24-hour standard of 35 µg/m^3, revised in 2006.

On January 22, 2010, the U.S. EPA established a new national 1-hour NO_2 standard of 100 parts per billion (ppb) and retained the annual average standard of 53 ppb. Designations for the primary NO_2 standard became effective on February 29, 2012. All areas of California meet this standard.

Sulfur Dioxide (SO_2). The U.S. EPA uses three categories to designate areas with respect to the 24-hour and annual average sulfur dioxide standards. These designation categories are:

- Nonattainment (N),
- Unclassifiable (U), and
- Unclassifiable/Attainment (U/A).

On June 2, 2010, the U.S. EPA established a new primary 1-hour SO_2 standard of 75 parts per billion (ppb). At the same time, U.S. EPA revoked the 24-hour and annual average standards. Area designations for the 1-hour SO_2 standard were finalized on December 21, 2017 and are reflected in the area designations map.

Lead (particulate). The U.S. EPA promulgated a new rolling 3-month average lead standard in October 2008 of 0.15 µg/m^3. Designations were made for this standard in November 2010.

Designation Areas

From time to time, the boundaries of the California air basins have been changed to facilitate the planning process. CARB generally initiates these changes, and they are not always reflected in the U.S. EPA's area designations. For purposes of consistency, the maps in this attachment reflect area designation boundaries and nomenclature as promulgated by the U.S. EPA. In some cases, these may not be the same as those adopted by CARB. For example, the national area designations reflect the former Southeast Desert Air Basin. In accordance with Health and Safety Code section 39606.1, CARB redefined this area in 1996 to be the Mojave Desert Air Basin and Salton Sea Air Basin. The definitions and boundaries for all areas designated for the national standards can be found in Title 40, Code of Federal Regulations (CFR), Chapter I, Subchapter C, Part 81.305. They are available on the web at: *https://ecfr.io/Title-40/se40.20.81_1305*

[1] Air quality in Sacramento County meets the national PM_{10} standards. The request for redesignation to attainment was approved by U.S. EPA in September 2013.

[2] The request for redesignation to attainment for the Imperial Valley Planning Area was approved by U.S. EPA in September 2020, effective October 2020.

* Definitions and references for all areas can be found in 40 CFR, Chapter I, Part 81.305. This map reflects the 2006 24-hour $PM_{2.5}$ standard as well as the 1997 and 2012 $PM_{2.5}$ annual standards.

[1] For this purpose, Sacramento Metro Area comprises all of Sacramento and portions of El Dorado, Placer, Solano, and Yolo Counties. Air quality in this area meets the national $PM_{2.5}$ standards. A Determination of Attainment for the 2006 24-hour $PM_{2.5}$ standard was made by U.S. EPA in June 2017.

[2] Air quality in this area meets the national $PM_{2.5}$ standards. A Determination of Attainment for the 2006 24-hour $PM_{2.5}$ standard was made by U.S. EPA in June 2017.

[3] Those lands of the Santa Rosa Band of Cahulla Mission Indians in Riverside County are designated Unclassifiable/Attainment.

[4] That portion of Imperial County encompassing the urban and surrounding areas of Brawley, Calexico, El Centro, Heber, Holtville, Imperial, Seeley, and Westmorland. Air quality in this area meets the national $PM_{2.5}$ standards. A Determination of Attainment for the 2006 24-hour $PM_{2.5}$ standard was made by U.S. EPA in June 2017.

1. Basic Project Information

1.1. Basic Project Information

Data Field	Value
Project Name	15309-WWTP Upgrades (Unmitigated)
Construction Start Date	1/1/2025
Operational Year	2027
Lead Agency	—
Land Use Scale	Project/site
Analysis Level for Defaults	County
Windspeed (m/s)	2.50
Precipitation (days)	1.80
Location	34.269428, -116.815824
County	San Bernardino-South Coast
City	Unincorporated
Air District	South Coast AQMD
Air Basin	South Coast
TAZ	5156
EDFZ	10
Electric Utility	Bear Valley Electric Service
Gas Utility	Southwest Gas Corp.
App Version	2022.1.1.18

1.2. Land Use Types

Land Use Subtype	Size	Unit	Lot Acreage	Building Area (sq ft)	Landscape Area (sq ft)	Special Landscape Area (sq ft)	Population	Description

Unrefrigerated Warehouse-Rail	40.0	1000sqft	0.92	40,000	0.00	—	—	—
Other Non-Asphalt Surfaces	2.00	Acre	2.00	0.00	0.00	—	—	Pump Station
Parking Lot	0.50	Acre	0.50	0.00	0.00	—	—	—
User Defined Linear	0.26	Mile	0.14	0.00	0.00	—	—	—
Other Asphalt Surfaces	0.44	Acre	0.44	0.00	0.00	—	—	Remaining SF

1.3. User-Selected Emission Reduction Measures by Emissions Sector

Sector	#	Measure Title
Energy	E-10-B	Establish Onsite Renewable Energy Systems: Solar Power

2. Emissions Summary

2.1. Construction Emissions Compared Against Thresholds

Criteria Pollutants (lb/day for daily, ton/yr for annual) and GHGs (lb/day for daily, MT/yr for annual)

6. Climate Risk Detailed Report

6.1. Climate Risk Summary

Cal-Adapt midcentury 2040–2059 average projections for four hazards are reported below for your project location. These are under Representation Concentration Pathway (RCP) 8.5 which assumes GHG emissions will continue to rise strongly through 2050 and then plateau around 2100.

Climate Hazard	Result for Project Location	Unit
Temperature and Extreme Heat	38.6	annual days of extreme heat
Extreme Precipitation	7.50	annual days with precipitation above 20 mm
Sea Level Rise	0.00	meters of inundation depth
Wildfire	35.6	annual hectares burned

Temperature and Extreme Heat data are for grid cell in which your project are located. The projection is based on the 98th historical percentile of daily maximum/minimum temperatures from observed historical data (32 climate model ensemble from Cal-Adapt, 2040–2059 average under RCP 8.5). Each grid cell is 6 kilometers (km) by 6 km, or 3.7 miles (mi) by 3.7 mi.
Extreme Precipitation data are for the grid cell in which your project are located. The threshold of 20 mm is equivalent to about ¾ an inch of rain, which would be light to moderate rainfall if received over a full day or heavy rain if received over a period of 2 to 4 hours. Each grid cell is 6 kilometers (km) by 6 km, or 3.7 miles (mi) by 3.7 mi.
Sea Level Rise data are for the grid cell in which your project are located. The projections are from Radke et al. (2017), as reported in Cal-Adapt (2040–2059 average under RCP 8.5), and consider different increments of sea level rise coupled with extreme storm events. Users may select from four model simulations to view the range in potential inundation depth for the grid cell. The four simulations make different assumptions about expected rainfall and temperature are: Warmer/drier (HadGEM2-ES), Cooler/wetter (CNRM-CM5), Average conditions (CanESM2), Range of different rainfall and temperature possibilities (MIROC5). Each grid cell is 50 meters (m) by 50 m, or about 164 feet (ft) by 164 ft.

Wildfire data are for the grid cell in which your project are located. The projections are from UC Davis, as reported in Cal-Adapt (2040–2059 average under RCP 8.5), and consider historical data of climate, vegetation, population density, and large (> 400 ha) fire history. Users may select from four model simulations to view the range in potential wildfire probabilities for the grid cell. The four simulations make different assumptions about expected rainfall and temperature are: Warmer/drier (HadGEM2-ES), Cooler/wetter (CNRM-CM5), Average conditions (CanESM2), Range of different rainfall and temperature possibilities (MIROC5). Each grid cell is 6 kilometers (km) by 6 km, or 3.7 miles (mi) by 3.7 mi.

6.2. Initial Climate Risk Scores

Climate Hazard	Exposure Score	Sensitivity Score	Adaptive Capacity Score	Vulnerability Score
Temperature and Extreme Heat	5	0	0	N/A
Extreme Precipitation	N/A	N/A	N/A	N/A
Sea Level Rise	1	0	0	N/A
Wildfire	1	0	0	N/A
Flooding	N/A	N/A	N/A	N/A
Drought	N/A	N/A	N/A	N/A
Snowpack Reduction	N/A	N/A	N/A	N/A
Air Quality Degradation	0	0	0	N/A

The sensitivity score reflects the extent to which a project would be adversely affected by exposure to a climate hazard. Exposure is rated on a scale of 1 to 5, with a score of 5 representing the greatest exposure.
The adaptive capacity of a project refers to its ability to manage and reduce vulnerabilities from projected climate hazards. Adaptive capacity is rated on a scale of 1 to 5, with a score of 5 representing the greatest ability to adapt.
The overall vulnerability scores are calculated based on the potential impacts and adaptive capacity assessments for each hazard. Scores do not include implementation of climate risk reduction measures.

6.3. Adjusted Climate Risk Scores

Climate Hazard	Exposure Score	Sensitivity Score	Adaptive Capacity Score	Vulnerability Score
Temperature and Extreme Heat	5	1	1	4
Extreme Precipitation	N/A	N/A	N/A	N/A
Sea Level Rise	1	1	1	2
Wildfire	1	1	1	2
Flooding	N/A	N/A	N/A	N/A
Drought	N/A	N/A	N/A	N/A
Snowpack Reduction	N/A	N/A	N/A	N/A

Air Quality Degradation	1	1	1	2

The sensitivity score reflects the extent to which a project would be adversely affected by exposure to a climate hazard. Exposure is rated on a scale of 1 to 5, with a score of 5 representing the greatest exposure.
The adaptive capacity of a project refers to its ability to manage and reduce vulnerabilities from projected climate hazards. Adaptive capacity is rated on a scale of 1 to 5, with a score of 5 representing the greatest ability to adapt.
The overall vulnerability scores are calculated based on the potential impacts and adaptive capacity assessments for each hazard. Scores include implementation of climate risk reduction measures.

6.4. Climate Risk Reduction Measures

7. Health and Equity Details

7.1. CalEnviroScreen 4.0 Scores

The maximum CalEnviroScreen score is 100. A high score (i.e., greater than 50) reflects a higher pollution burden compared to other census tracts in the state.

Indicator	Result for Project Census Tract
Exposure Indicators	—
AQ-Ozone	97.6
AQ-PM	1.68
AQ-DPM	4.41
Drinking Water	60.7
Lead Risk Housing	11.6
Pesticides	11.0
Toxic Releases	8.39
Traffic	1.35
Effect Indicators	—
CleanUp Sites	0.00
Groundwater	0.00
Haz Waste Facilities/Generators	0.00
Impaired Water Bodies	0.00
Solid Waste	11.6

Sensitive Population	—
Asthma	63.6
Cardio-vascular	92.9
Low Birth Weights	66.3
Socioeconomic Factor Indicators	—
Education	33.5
Housing	22.1
Linguistic	8.49
Poverty	67.0
Unemployment	64.5

7.2. Healthy Places Index Scores

The maximum Health Places Index score is 100. A high score (i.e., greater than 50) reflects healthier community conditions compared to other census tracts in the state.

Indicator	Result for Project Census Tract
Economic	—
Above Poverty	54.07416913
Employed	2.34826126
Median HI	47.09354549
Education	—
Bachelor's or higher	24.38085461
High school enrollment	100
Preschool enrollment	95.7141024
Transportation	—
Auto Access	86.34672142
Active commuting	8.161170281
Social	—
2-parent households	29.38534582

Voting	73.38637239

Impervious Surface Cover	94.7
Traffic Density	3.7
Traffic Access	23.0
Other Indices	—
Hardship	62.9
Other Decision Support	—
2016 Voting	81.4

7.3. Overall Health & Equity Scores

Metric	Result for Project Census Tract
CalEnviroScreen 4.0 Score for Project Location (a)	19.0
Healthy Places Index Score for Project Location (b)	41.0
Project Located in a Designated Disadvantaged Community (Senate Bill 535)	No
Project Located in a Low-Income Community (Assembly Bill 1550)	No
Project Located in a Community Air Protection Program Community (Assembly Bill 617)	No

a: The maximum CalEnviroScreen score is 100. A high score (i.e., greater than 50) reflects a higher pollution burden compared to other census tracts in the state.
b: The maximum Health Places Index score is 100. A high score (i.e., greater than 50) reflects healthier community conditions compared to other census tracts in the state.

7.4. Health & Equity Measures

No Health & Equity Measures selected.

7.5. Evaluation Scorecard

Health & Equity Evaluation Scorecard not completed.

7.6. Health & Equity Custom Measures

No Health & Equity Custom Measures created.

8. User Changes to Default Data

Screen	Justification
Construction: Construction Phases	Based on Client Provided data and construction schedule
Construction: Off-Road Equipment	Client Provided construction equipment list
Construction: Trips and VMT	Per Project applicant, the hauling trucks would travel a distance of up to 100 miles round trip, as such hauling for both the Linear, Grading & Excavation and Demolition phase was adjusted to 100 miles.
Operations: Vehicle Data	No trips data available
Operations: Architectural Coatings	SCAQMD Rule 1113
Construction: Dust From Material Movement	Export expected per Project data

Construction: Architectural Coatings	SCAQMD Rule 1113
Operations: Energy Use	Electricity adjusted based on client provided data
Operations: Water and Waste Water	Taken from 2022 Lake Analysis report

2.5. Operations Emissions by Sector, Unmitigated

3. Construction Emissions Details

3.1. Linear, Grading & Excavation (2025) - Unmitigated

3.3. Linear, Grading & Excavation (2026) - Unmitigated

3.5. Linear, Drainage, Utilities, & Sub-Grade (2026) - Unmitigated

3.7. Demolition (2025) - Unmitigated

4. Operations Emissions Details

4.1. Mobile Emissions by Land Use

4.1.1. Unmitigated

4.2. Energy

4.2.1. Electricity Emissions By Land Use - Unmitigated

4.2.3. Natural Gas Emissions By Land Use - Unmitigated

4.3. Area Emissions by Source

4.3.1. Unmitigated

4.4. Water Emissions by Land Use

4.4.1. Unmitigated

4.5. Waste Emissions by Land Use

4.5.1. Unmitigated

4.6. Refrigerant Emissions by Land Use

4.6.1. Unmitigated

4.7. Offroad Emissions By Equipment Type

4.7.1. Unmitigated

4.8. Stationary Emissions By Equipment Type

4.8.1. Unmitigated

4.9. User Defined Emissions By Equipment Type

4.9.1. Unmitigated

4.10. Soil Carbon Accumulation By Vegetation Type

4.10.1. Soil Carbon Accumulation By Vegetation Type - Unmitigated

4.10.2. Above and Belowground Carbon Accumulation by Land Use Type - Unmitigated

4.10.3. Avoided and Sequestered Emissions by Species - Unmitigated

6. Climate Risk Detailed Report

6.1. Climate Risk Summary

6.2. Initial Climate Risk Scores

6.3. Adjusted Climate Risk Scores

6.4. Climate Risk Reduction Measures

7. Health and Equity Details

7.1. CalEnviroScreen 4.0 Scores

7.2. Healthy Places Index Scores

7.3. Overall Health & Equity Scores

7.4. Health & Equity Measures

7.5. Evaluation Scorecard

7.6. Health & Equity Custom Measures

8. User Changes to Default Data

1. Basic Project Information

1.1. Basic Project Information

Data Field	Value
Project Name	15309-Lake Pipeline (Unmitigated)
Construction Start Date	5/1/2025
Operational Year	2027
Lead Agency	—
Land Use Scale	Project/site
Analysis Level for Defaults	County
Windspeed (m/s)	2.50
Precipitation (days)	1.80
Location	34.269428, -116.815824
County	San Bernardino-South Coast
City	Unincorporated
Air District	South Coast AQMD
Air Basin	South Coast
TAZ	5156
EDFZ	10
Electric Utility	Bear Valley Electric Service
Gas Utility	Southwest Gas Corp.
App Version	2022.1.1.18

1.2. Land Use Types

Land Use Subtype	Size	Unit	Lot Acreage	Building Area (sq ft)	Landscape Area (sq ft)	Special Landscape Area (sq ft)	Population	Description

User Defined Linear	3.78	Mile	2.06	0.00	—	—	—	—
Other Non-Asphalt Surfaces	1.00	Acre	1.00	0.00	0.00	—	—	—

1.3. User-Selected Emission Reduction Measures by Emissions Sector

No measures selected

2. Emissions Summary

2.1. Construction Emissions Compared Against Thresholds

5.18.2.1. Unmitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

6. Climate Risk Detailed Report

6.1. Climate Risk Summary

Cal-Adapt midcentury 2040–2059 average projections for four hazards are reported below for your project location. These are under Representation Concentration Pathway (RCP) 8.5 which assumes GHG emissions will continue to rise strongly through 2050 and then plateau around 2100.

Climate Hazard	Result for Project Location	Unit
Temperature and Extreme Heat	38.6	annual days of extreme heat
Extreme Precipitation	7.50	annual days with precipitation above 20 mm
Sea Level Rise	0.00	meters of inundation depth
Wildfire	35.6	annual hectares burned

Temperature and Extreme Heat data are for grid cell in which your project are located. The projection is based on the 98th historical percentile of daily maximum/minimum temperatures from observed historical data (32 climate model ensemble from Cal-Adapt, 2040–2059 average under RCP 8.5). Each grid cell is 6 kilometers (km) by 6 km, or 3.7 miles (mi) by 3.7 mi.
Extreme Precipitation data are for the grid cell in which your project are located. The threshold of 20 mm is equivalent to about ¾ an inch of rain, which would be light to moderate rainfall if received over a full day or heavy rain if received over a period of 2 to 4 hours. Each grid cell is 6 kilometers (km) by 6 km, or 3.7 miles (mi) by 3.7 mi.

Sea Level Rise data are for the grid cell in which your project are located. The projections are from Radke et al. (2017), as reported in Cal-Adapt (2040–2059 average under RCP 8.5), and consider different increments of sea level rise coupled with extreme storm events. Users may select from four model simulations to view the range in potential inundation depth for the grid cell. The four simulations make different assumptions about expected rainfall and temperature are: Warmer/drier (HadGEM2-ES), Cooler/wetter (CNRM-CM5), Average conditions (CanESM2), Range of different rainfall and temperature possibilities (MIROC5). Each grid cell is 50 meters (m) by 50 m, or about 164 feet (ft) by 164 ft.
Wildfire data are for the grid cell in which your project are located. The projections are from UC Davis, as reported in Cal-Adapt (2040–2059 average under RCP 8.5), and consider historical data of climate, vegetation, population density, and large (> 400 ha) fire history. Users may select from four model simulations to view the range in potential wildfire probabilities for the grid cell. The four simulations make different assumptions about expected rainfall and temperature are: Warmer/drier (HadGEM2-ES), Cooler/wetter (CNRM-CM5), Average conditions (CanESM2), Range of different rainfall and temperature possibilities (MIROC5). Each grid cell is 6 kilometers (km) by 6 km, or 3.7 miles (mi) by 3.7 mi.

6.2. Initial Climate Risk Scores

Climate Hazard	Exposure Score	Sensitivity Score	Adaptive Capacity Score	Vulnerability Score
Temperature and Extreme Heat	5	0	0	N/A
Extreme Precipitation	N/A	N/A	N/A	N/A
Sea Level Rise	1	0	0	N/A
Wildfire	1	0	0	N/A
Flooding	N/A	N/A	N/A	N/A
Drought	N/A	N/A	N/A	N/A
Snowpack Reduction	N/A	N/A	N/A	N/A
Air Quality Degradation	0	0	0	N/A

The sensitivity score reflects the extent to which a project would be adversely affected by exposure to a climate hazard. Exposure is rated on a scale of 1 to 5, with a score of 5 representing the greatest exposure.
The adaptive capacity of a project refers to its ability to manage and reduce vulnerabilities from projected climate hazards. Adaptive capacity is rated on a scale of 1 to 5, with a score of 5 representing the greatest ability to adapt.
The overall vulnerability scores are calculated based on the potential impacts and adaptive capacity assessments for each hazard. Scores do not include implementation of climate risk reduction measures.

6.3. Adjusted Climate Risk Scores

Climate Hazard	Exposure Score	Sensitivity Score	Adaptive Capacity Score	Vulnerability Score
Temperature and Extreme Heat	5	1	1	4
Extreme Precipitation	N/A	N/A	N/A	N/A
Sea Level Rise	1	1	1	2
Wildfire	1	1	1	2
Flooding	N/A	N/A	N/A	N/A

Drought	N/A	N/A	N/A	N/A
Snowpack Reduction	N/A	N/A	N/A	N/A
Air Quality Degradation	1	1	1	2

The sensitivity score reflects the extent to which a project would be adversely affected by exposure to a climate hazard. Exposure is rated on a scale of 1 to 5, with a score of 5 representing the greatest exposure.
The adaptive capacity of a project refers to its ability to manage and reduce vulnerabilities from projected climate hazards. Adaptive capacity is rated on a scale of 1 to 5, with a score of 5 representing the greatest ability to adapt.
The overall vulnerability scores are calculated based on the potential impacts and adaptive capacity assessments for each hazard. Scores include implementation of climate risk reduction measures.

6.4. Climate Risk Reduction Measures

7. Health and Equity Details

7.1. CalEnviroScreen 4.0 Scores

The maximum CalEnviroScreen score is 100. A high score (i.e., greater than 50) reflects a higher pollution burden compared to other census tracts in the state.

Indicator	Result for Project Census Tract
Exposure Indicators	—
AQ-Ozone	97.6
AQ-PM	1.68
AQ-DPM	4.41
Drinking Water	60.7
Lead Risk Housing	11.6
Pesticides	11.0
Toxic Releases	8.39
Traffic	1.35
Effect Indicators	—
CleanUp Sites	0.00
Groundwater	0.00
Haz Waste Facilities/Generators	0.00

Impaired Water Bodies	0.00
Solid Waste	11.6
Sensitive Population	—
Asthma	63.6
Cardio-vascular	92.9
Low Birth Weights	66.3
Socioeconomic Factor Indicators	—
Education	33.5
Housing	22.1
Linguistic	8.49
Poverty	67.0
Unemployment	64.5

7.2. Healthy Places Index Scores

The maximum Health Places Index score is 100. A high score (i.e., greater than 50) reflects healthier community conditions compared to other census tracts in the state.

Indicator	Result for Project Census Tract
Economic	—
Above Poverty	54.07416913
Employed	2.34826126
Median HI	47.09354549
Education	—

7.3. Overall Health & Equity Scores

Metric	Result for Project Census Tract
CalEnviroScreen 4.0 Score for Project Location (a)	19.0
Healthy Places Index Score for Project Location (b)	41.0
Project Located in a Designated Disadvantaged Community (Senate Bill 535)	No
Project Located in a Low-Income Community (Assembly Bill 1550)	No
Project Located in a Community Air Protection Program Community (Assembly Bill 617)	No

a: The maximum CalEnviroScreen score is 100. A high score (i.e., greater than 50) reflects a higher pollution burden compared to other census tracts in the state.
b: The maximum Health Places Index score is 100. A high score (i.e., greater than 50) reflects healthier community conditions compared to other census tracts in the state.

7.4. Health & Equity Measures

No Health & Equity Measures selected.

7.5. Evaluation Scorecard

Health & Equity Evaluation Scorecard not completed.

7.6. Health & Equity Custom Measures

No Health & Equity Custom Measures created.

8. User Changes to Default Data

Screen	Justification
Construction: Construction Phases	Client Provided Schedule
Construction: Off-Road Equipment	Client Provided Equipment list
Construction: Trips and VMT	13 haul trucks and 2 worker trucks accounted for in Linear, Grading & Excavation Phase in addition to default CalEEMod hauling trucks. Per Project applicant, the hauling trucks would travel a distance of up to 100 miles round trip, as such hauling for both the Linear, Grading & Excavation and Demolition phase was adjusted to 100 miles.

5.6.2. Construction Earthmoving Control Strategies

Control Strategies Applied	Frequency (per day)	PM10 Reduction	PM2.5 Reduction
Water Exposed Area	3	74%	74%

5.7. Construction Paving

Land Use	Area Paved (acres)	% Asphalt
User Defined Linear	0.65	100%

5.8. Construction Electricity Consumption and Emissions Factors

kWh per Year and Emission Factor (lb/MWh)

Year	kWh per Year	CO2	CH4	N2O
2025	29.4	565	0.03	< 0.005
2026	29.4	482	0.03	< 0.005

5.18. Vegetation

5.18.1. Land Use Change

5.18.1.1. Unmitigated

Vegetation Land Use Type	Vegetation Soil Type	Initial Acres	Final Acres

5.18.1. Biomass Cover Type

5.18.1.1. Unmitigated

Biomass Cover Type	Initial Acres	Final Acres

5.18.2. Sequestration

5.18.2.1. Unmitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

6. Climate Risk Detailed Report

6.1. Climate Risk Summary

Cal-Adapt midcentury 2040–2059 average projections for four hazards are reported below for your project location. These are under Representation Concentration Pathway (RCP) 8.5 which assumes GHG emissions will continue to rise strongly through 2050 and then plateau around 2100.

Climate Hazard	Result for Project Location	Unit
Temperature and Extreme Heat	39.3	annual days of extreme heat
Extreme Precipitation	4.40	annual days with precipitation above 20 mm
Sea Level Rise	0.00	meters of inundation depth
Wildfire	31.0	annual hectares burned

Temperature and Extreme Heat data are for grid cell in which your project are located. The projection is based on the 98th historical percentile of daily maximum/minimum temperatures from observed historical data (32 climate model ensemble from Cal-Adapt, 2040–2059 average under RCP 8.5). Each grid cell is 6 kilometers (km) by 6 km, or 3.7 miles (mi) by 3.7 mi.
Extreme Precipitation data are for the grid cell in which your project are located. The threshold of 20 mm is equivalent to about ¾ an inch of rain, which would be light to moderate rainfall if received over a full day or heavy rain if received over a period of 2 to 4 hours. Each grid cell is 6 kilometers (km) by 6 km, or 3.7 miles (mi) by 3.7 mi.

Sea Level Rise data are for the grid cell in which your project are located. The projections are from Radke et al. (2017), as reported in Cal-Adapt (2040–2059 average under RCP 8.5), and consider different increments of sea level rise coupled with extreme storm events. Users may select from four model simulations to view the range in potential inundation depth for the grid cell. The four simulations make different assumptions about expected rainfall and temperature are: Warmer/drier (HadGEM2-ES), Cooler/wetter (CNRM-CM5), Average conditions (CanESM2), Range of different rainfall and temperature possibilities (MIROC5). Each grid cell is 50 meters (m) by 50 m, or about 164 feet (ft) by 164 ft.
Wildfire data are for the grid cell in which your project are located. The projections are from UC Davis, as reported in Cal-Adapt (2040–2059 average under RCP 8.5), and consider historical data of climate, vegetation, population density, and large (> 400 ha) fire history. Users may select from four model simulations to view the range in potential wildfire probabilities for the grid cell. The four simulations make different assumptions about expected rainfall and temperature are: Warmer/drier (HadGEM2-ES), Cooler/wetter (CNRM-CM5), Average conditions (CanESM2), Range of different rainfall and temperature possibilities (MIROC5). Each grid cell is 6 kilometers (km) by 6 km, or 3.7 miles (mi) by 3.7 mi.

6.2. Initial Climate Risk Scores

Climate Hazard	Exposure Score	Sensitivity Score	Adaptive Capacity Score	Vulnerability Score
Temperature and Extreme Heat	5	0	0	N/A
Extreme Precipitation	N/A	N/A	N/A	N/A
Sea Level Rise	1	0	0	N/A
Wildfire	1	0	0	N/A
Flooding	N/A	N/A	N/A	N/A
Drought	N/A	N/A	N/A	N/A
Snowpack Reduction	N/A	N/A	N/A	N/A
Air Quality Degradation	0	0	0	N/A

The sensitivity score reflects the extent to which a project would be adversely affected by exposure to a climate hazard. Exposure is rated on a scale of 1 to 5, with a score of 5 representing the greatest exposure.
The adaptive capacity of a project refers to its ability to manage and reduce vulnerabilities from projected climate hazards. Adaptive capacity is rated on a scale of 1 to 5, with a score of 5 representing the greatest ability to adapt.
The overall vulnerability scores are calculated based on the potential impacts and adaptive capacity assessments for each hazard. Scores do not include implementation of climate risk reduction measures.

6.3. Adjusted Climate Risk Scores

Climate Hazard	Exposure Score	Sensitivity Score	Adaptive Capacity Score	Vulnerability Score
Temperature and Extreme Heat	5	1	1	4
Extreme Precipitation	N/A	N/A	N/A	N/A
Sea Level Rise	1	1	1	2
Wildfire	1	1	1	2
Flooding	N/A	N/A	N/A	N/A

Drought	N/A	N/A	N/A	N/A
Snowpack Reduction	N/A	N/A	N/A	N/A
Air Quality Degradation	1	1	1	2

The sensitivity score reflects the extent to which a project would be adversely affected by exposure to a climate hazard. Exposure is rated on a scale of 1 to 5, with a score of 5 representing the greatest exposure.
The adaptive capacity of a project refers to its ability to manage and reduce vulnerabilities from projected climate hazards. Adaptive capacity is rated on a scale of 1 to 5, with a score of 5 representing the greatest ability to adapt.
The overall vulnerability scores are calculated based on the potential impacts and adaptive capacity assessments for each hazard. Scores include implementation of climate risk reduction measures.

6.4. Climate Risk Reduction Measures

7. Health and Equity Details

7.1. CalEnviroScreen 4.0 Scores

The maximum CalEnviroScreen score is 100. A high score (i.e., greater than 50) reflects a higher pollution burden compared to other census tracts in the state.

Indicator	Result for Project Census Tract
Exposure Indicators	—
AQ-Ozone	97.6
AQ-PM	1.68
AQ-DPM	4.41
Drinking Water	60.7
Lead Risk Housing	11.6
Pesticides	11.0
Toxic Releases	8.39
Traffic	1.35
Effect Indicators	—
CleanUp Sites	0.00
Groundwater	0.00
Haz Waste Facilities/Generators	0.00

Impaired Water Bodies	0.00
Solid Waste	11.6
Sensitive Population	—
Asthma	63.6
Cardio-vascular	92.9
Low Birth Weights	66.3
Socioeconomic Factor Indicators	—
Education	33.5
Housing	22.1
Linguistic	8.49
Poverty	67.0
Unemployment	64.5

7.2. Healthy Places Index Scores

The maximum Health Places Index score is 100. A high score (i.e., greater than 50) reflects healthier community conditions compared to other census tracts in the state.

Indicator	Result for Project Census Tract
Economic	—
Above Poverty	54.07416913
Employed	2.34826126
Median HI	47.09354549
Education	—
Bachelor's or higher	24.38085461

7.3. Overall Health & Equity Scores

Metric	Result for Project Census Tract
CalEnviroScreen 4.0 Score for Project Location (a)	19.0
Healthy Places Index Score for Project Location (b)	41.0
Project Located in a Designated Disadvantaged Community (Senate Bill 535)	No
Project Located in a Low-Income Community (Assembly Bill 1550)	No
Project Located in a Community Air Protection Program Community (Assembly Bill 617)	No

a: The maximum CalEnviroScreen score is 100. A high score (i.e., greater than 50) reflects a higher pollution burden compared to other census tracts in the state.
b: The maximum Health Places Index score is 100. A high score (i.e., greater than 50) reflects healthier community conditions compared to other census tracts in the state.

7.4. Health & Equity Measures

No Health & Equity Measures selected.

7.5. Evaluation Scorecard

Health & Equity Evaluation Scorecard not completed.

7.6. Health & Equity Custom Measures

No Health & Equity Custom Measures created.

8. User Changes to Default Data

Screen	Justification
Construction: Construction Phases	Client Provided Schedule
Construction: Off-Road Equipment	Client Provided Equipment list
Construction: Trips and VMT	13 haul trucks and 2 worker trucks accounted for in Linear, Grading & Excavation Phase.

6. Climate Risk Detailed Report

6.1. Climate Risk Summary

Cal-Adapt midcentury 2040–2059 average projections for four hazards are reported below for your project location. These are under Representation Concentration Pathway (RCP) 8.5 which assumes GHG emissions will continue to rise strongly through 2050 and then plateau around 2100.

Climate Hazard	Result for Project Location	Unit
Temperature and Extreme Heat	38.6	annual days of extreme heat
Extreme Precipitation	7.50	annual days with precipitation above 20 mm
Sea Level Rise	0.00	meters of inundation depth
Wildfire	35.6	annual hectares burned

Temperature and Extreme Heat data are for grid cell in which your project are located. The projection is based on the 98th historical percentile of daily maximum/minimum temperatures from observed historical data (32 climate model ensemble from Cal-Adapt, 2040–2059 average under RCP 8.5). Each grid cell is 6 kilometers (km) by 6 km, or 3.7 miles (mi) by 3.7 mi.
Extreme Precipitation data are for the grid cell in which your project are located. The threshold of 20 mm is equivalent to about ¾ an inch of rain, which would be light to moderate rainfall if received over a full day or heavy rain if received over a period of 2 to 4 hours. Each grid cell is 6 kilometers (km) by 6 km, or 3.7 miles (mi) by 3.7 mi.
Sea Level Rise data are for the grid cell in which your project are located. The projections are from Radke et al. (2017), as reported in Cal-Adapt (2040–2059 average under RCP 8.5), and consider different increments of sea level rise coupled with extreme storm events. Users may select from four model simulations to view the range in potential inundation depth for the grid cell. The four simulations make different assumptions about expected rainfall and temperature are: Warmer/drier (HadGEM2-ES), Cooler/wetter (CNRM-CM5), Average conditions (CanESM2), Range of different rainfall and temperature possibilities (MIROC5). Each grid cell is 50 meters (m) by 50 m, or about 164 feet (ft) by 164 ft.
Wildfire data are for the grid cell in which your project are located. The projections are from UC Davis, as reported in Cal-Adapt (2040–2059 average under RCP 8.5), and consider historical data of climate, vegetation, population density, and large (> 400 ha) fire history. Users may select from four model simulations to view the range in potential wildfire probabilities for the grid cell. The four simulations make different assumptions about expected rainfall and temperature are: Warmer/drier (HadGEM2-ES), Cooler/wetter (CNRM-CM5), Average conditions (CanESM2), Range of different rainfall and temperature possibilities (MIROC5). Each grid cell is 6 kilometers (km) by 6 km, or 3.7 miles (mi) by 3.7 mi.

6.2. Initial Climate Risk Scores

Climate Hazard	Exposure Score	Sensitivity Score	Adaptive Capacity Score	Vulnerability Score
Temperature and Extreme Heat	5	0	0	N/A

Extreme Precipitation	N/A	N/A	N/A	N/A
Sea Level Rise	1	0	0	N/A
Wildfire	1	0	0	N/A
Flooding	N/A	N/A	N/A	N/A
Drought	N/A	N/A	N/A	N/A
Snowpack Reduction	N/A	N/A	N/A	N/A
Air Quality Degradation	0	0	0	N/A

The sensitivity score reflects the extent to which a project would be adversely affected by exposure to a climate hazard. Exposure is rated on a scale of 1 to 5, with a score of 5 representing the greatest exposure.
The adaptive capacity of a project refers to its ability to manage and reduce vulnerabilities from projected climate hazards. Adaptive capacity is rated on a scale of 1 to 5, with a score of 5 representing the greatest ability to adapt.
The overall vulnerability scores are calculated based on the potential impacts and adaptive capacity assessments for each hazard. Scores do not include implementation of climate risk reduction measures.

6.3. Adjusted Climate Risk Scores

Climate Hazard	Exposure Score	Sensitivity Score	Adaptive Capacity Score	Vulnerability Score
Temperature and Extreme Heat	5	1	1	4
Extreme Precipitation	N/A	N/A	N/A	N/A
Sea Level Rise	1	1	1	2
Wildfire	1	1	1	2
Flooding	N/A	N/A	N/A	N/A
Drought	N/A	N/A	N/A	N/A
Snowpack Reduction	N/A	N/A	N/A	N/A
Air Quality Degradation	1	1	1	2

The sensitivity score reflects the extent to which a project would be adversely affected by exposure to a climate hazard. Exposure is rated on a scale of 1 to 5, with a score of 5 representing the greatest exposure.
The adaptive capacity of a project refers to its ability to manage and reduce vulnerabilities from projected climate hazards. Adaptive capacity is rated on a scale of 1 to 5, with a score of 5 representing the greatest ability to adapt.
The overall vulnerability scores are calculated based on the potential impacts and adaptive capacity assessments for each hazard. Scores include implementation of climate risk reduction measures.

6.4. Climate Risk Reduction Measures

7. Health and Equity Details

7.1. CalEnviroScreen 4.0 Scores

The maximum CalEnviroScreen score is 100. A high score (i.e., greater than 50) reflects a higher pollution burden compared to other census tracts in the state.

Indicator	Result for Project Census Tract
Exposure Indicators	—
AQ-Ozone	97.6
AQ-PM	1.68
AQ-DPM	4.41
Drinking Water	60.7
Lead Risk Housing	11.6
Pesticides	11.0
Toxic Releases	8.39
Traffic	1.35
Effect Indicators	—
CleanUp Sites	0.00
Groundwater	0.00
Haz Waste Facilities/Generators	0.00
Impaired Water Bodies	0.00
Solid Waste	11.6
Sensitive Population	—
Asthma	63.6
Cardio-vascular	92.9
Low Birth Weights	66.3
Socioeconomic Factor Indicators	—
Education	33.5
Housing	22.1

Linguistic	8.49
Poverty	67.0
Unemployment	64.5

7.2. Healthy Places Index Scores

The maximum Health Places Index score is 100. A high score (i.e., greater than 50) reflects healthier community conditions compared to other census tracts in the state.

Indicator	Result for Project Census Tract
Economic	—
Above Poverty	54.07416913
Employed	2.34826126
Median HI	47.09354549
Education	—
Bachelor's or higher	24.38085461
High school enrollment	100
Preschool enrollment	95.7141024
Transportation	—
Auto Access	86.34672142
Active commuting	8.161170281
Social	—
2-parent households	29.38534582
Voting	73.38637239
Neighborhood	—
Alcohol availability	87.1423072
Park access	51.00731426
Retail density	9.110740408
Supermarket access	10.57359168
Tree canopy	85.29449506

Housing	—
Homeownership	77.15898884
Housing habitability	49.54446298
Low-inc homeowner severe housing cost burden	35.91684845
Low-inc renter severe housing cost burden	3.708456307
Uncrowded housing	96.93314513
Health Outcomes	—
Insured adults	30.92518927
Arthritis	0.0
Asthma ER Admissions	46.4
High Blood Pressure	0.0
Cancer (excluding skin)	0.0
Asthma	0.0
Coronary Heart Disease	0.0
Chronic Obstructive Pulmonary Disease	0.0
Diagnosed Diabetes	0.0
Life Expectancy at Birth	16.7
Cognitively Disabled	5.2
Physically Disabled	5.0
Heart Attack ER Admissions	10.8
Mental Health Not Good	0.0
Chronic Kidney Disease	0.0
Obesity	0.0
Pedestrian Injuries	59.1
Physical Health Not Good	0.0
Stroke	0.0
Health Risk Behaviors	—

Binge Drinking	0.0
Current Smoker	0.0
No Leisure Time for Physical Activity	0.0
Climate Change Exposures	—
Wildfire Risk	87.1
SLR Inundation Area	0.0

Climate Change Adaptive Capacity	—
Impervious Surface Cover	94.7
Traffic Density	3.7
Traffic Access	23.0
Other Indices	—
Hardship	62.9
Other Decision Support	—
2016 Voting	81.4

7.3. Overall Health & Equity Scores

Metric	Result for Project Census Tract
CalEnviroScreen 4.0 Score for Project Location (a)	19.0
Healthy Places Index Score for Project Location (b)	41.0
Project Located in a Designated Disadvantaged Community (Senate Bill 535)	No
Project Located in a Low-Income Community (Assembly Bill 1550)	No
Project Located in a Community Air Protection Program Community (Assembly Bill 617)	No

a: The maximum CalEnviroScreen score is 100. A high score (i.e., greater than 50) reflects a higher pollution burden compared to other census tracts in the state.
b: The maximum Health Places Index score is 100. A high score (i.e., greater than 50) reflects healthier community conditions compared to other census tracts in the state.

7.4. Health & Equity Measures

No Health & Equity Measures selected.

7.5. Evaluation Scorecard

Health & Equity Evaluation Scorecard not completed.

7.6. Health & Equity Custom Measures

No Health & Equity Custom Measures created.

8. User Changes to Default Data

Screen	Justification
Construction: Construction Phases	Client Provided schedule
Construction: Off-Road Equipment	Client provided equipment list
Construction: Trips and VMT	Client provided total worker trips and hauling trips which equals 8,000 round trips.

CALEEMOD REPLENISH BIG BEAR COMPONENT 5 UNMITIGATED EMISSIONS MODEL OUTPUTS

15309-Sand Canyon Detailed Report

Table of Contents

1. Basic Project Information

1.1. Basic Project Information

1.2. Land Use Types

1.3. User-Selected Emission Reduction Measures by Emissions Sector

2. Emissions Summary

2.1. Construction Emissions Compared Against Thresholds

2.2. Construction Emissions by Year, Unmitigated

2.4. Operations Emissions Compared Against Thresholds

2.5. Operations Emissions by Sector, Unmitigated

3. Construction Emissions Details

3.1. Linear, Grading & Excavation (2025) - Unmitigated

3.3. Linear, Grading & Excavation (2026) - Unmitigated

3.5. Linear, Drainage, Utilities, & Sub-Grade (2026) - Unmitigated

3.7. Demolition (2025) - Unmitigated

3.9. Building Construction (2025) - Unmitigated

3.11. Building Construction (2026) - Unmitigated

4. Operations Emissions Details

4.1. Mobile Emissions by Land Use

4.1.1. Unmitigated

4.2. Energy

4.2.1. Electricity Emissions By Land Use - Unmitigated

4.2.3. Natural Gas Emissions By Land Use - Unmitigated

4.3. Area Emissions by Source

4.3.2. Unmitigated

4.4. Water Emissions by Land Use

4.4.2. Unmitigated

4.5. Waste Emissions by Land Use

4.5.2. Unmitigated

4.6. Refrigerant Emissions by Land Use

4.6.1. Unmitigated

4.7. Offroad Emissions By Equipment Type

4.7.1. Unmitigated

4.8. Stationary Emissions By Equipment Type

4.8.1. Unmitigated

4.9. User Defined Emissions By Equipment Type

4.9.1. Unmitigated

4.10. Soil Carbon Accumulation By Vegetation Type

4.10.1. Soil Carbon Accumulation By Vegetation Type - Unmitigated

4.10.2. Above and Belowground Carbon Accumulation by Land Use Type - Unmitigated

4.10.3. Avoided and Sequestered Emissions by Species - Unmitigated

5. Activity Data

5.1. Construction Schedule

5.2. Off-Road Equipment

5.2.1. Unmitigated

5.3. Construction Vehicles

5.3.1. Unmitigated

5.4. Vehicles

5.4.1. Construction Vehicle Control Strategies

5.5. Architectural Coatings

5.6. Dust Mitigation

5.6.1. Construction Earthmoving Activities

5.6.2. Construction Earthmoving Control Strategies

5.7. Construction Paving

5.8. Construction Electricity Consumption and Emissions Factors

5.9. Operational Mobile Sources

5.9.1. Unmitigated

5.10. Operational Area Sources

5.10.1. Hearths

5.10.1.1. Unmitigated

5.10.2. Architectural Coatings

5.10.3. Landscape Equipment

5.11. Operational Energy Consumption

5.11.1. Unmitigated

5.12. Operational Water and Wastewater Consumption

5.12.1. Unmitigated

5.13. Operational Waste Generation

5.13.1. Unmitigated

5.14. Operational Refrigeration and Air Conditioning Equipment

5.14.1. Unmitigated

5.15. Operational Off-Road Equipment

5.15.1. Unmitigated

5.16. Stationary Sources

5.16.1. Emergency Generators and Fire Pumps

5.16.2. Process Boilers

5.17. User Defined

5.18. Vegetation

5.18.1. Land Use Change

5.18.1.1. Unmitigated

5.18.1. Biomass Cover Type

5.18.1.1. Unmitigated

5.18.2. Sequestration

5.18.2.1. Unmitigated

5.18.2.1. Unmitigated

Tree Type	Number	Electricity Saved (kWh/year)	Natural Gas Saved (btu/year)

6. Climate Risk Detailed Report

6.1. Climate Risk Summary

Cal-Adapt midcentury 2040–2059 average projections for four hazards are reported below for your project location. These are under Representation Concentration Pathway (RCP) 8.5 which assumes GHG emissions will continue to rise strongly through 2050 and then plateau around 2100.

Climate Hazard	Result for Project Location	Unit
Temperature and Extreme Heat	38.1	annual days of extreme heat
Extreme Precipitation	8.60	annual days with precipitation above 20 mm
Sea Level Rise	0.00	meters of inundation depth
Wildfire	32.4	annual hectares burned

Temperature and Extreme Heat data are for grid cell in which your project are located. The projection is based on the 98th historical percentile of daily maximum/minimum temperatures from observed historical data (32 climate model ensemble from Cal-Adapt, 2040–2059 average under RCP 8.5). Each grid cell is 6 kilometers (km) by 6 km, or 3.7 miles (mi) by 3.7 mi.
Extreme Precipitation data are for the grid cell in which your project are located. The threshold of 20 mm is equivalent to about ¾ an inch of rain, which would be light to moderate rainfall if received over a full day or heavy rain if received over a period of 2 to 4 hours. Each grid cell is 6 kilometers (km) by 6 km, or 3.7 miles (mi) by 3.7 mi.
Sea Level Rise data are for the grid cell in which your project are located. The projections are from Radke et al. (2017), as reported in Cal-Adapt (2040–2059 average under RCP 8.5), and consider different increments of sea level rise coupled with extreme storm events. Users may select from four model simulations to view the range in potential inundation depth for the grid cell. The four simulations make different assumptions about expected rainfall and temperature are: Warmer/drier (HadGEM2-ES), Cooler/wetter (CNRM-CM5), Average conditions (CanESM2), Range of different rainfall and temperature possibilities (MIROC5). Each grid cell is 50 meters (m) by 50 m, or about 164 feet (ft) by 164 ft.
Wildfire data are for the grid cell in which your project are located. The projections are from UC Davis, as reported in Cal-Adapt (2040–2059 average under RCP 8.5), and consider historical data of climate, vegetation, population density, and large (> 400 ha) fire history. Users may select from four model simulations to view the range in potential wildfire probabilities for the grid cell. The four simulations make different assumptions about expected rainfall and temperature are: Warmer/drier (HadGEM2-ES), Cooler/wetter (CNRM-CM5), Average conditions (CanESM2), Range of different rainfall and temperature possibilities (MIROC5). Each grid cell is 6 kilometers (km) by 6 km, or 3.7 miles (mi) by 3.7 mi.

6.2. Initial Climate Risk Scores

Climate Hazard	Exposure Score	Sensitivity Score	Adaptive Capacity Score	Vulnerability Score
Temperature and Extreme Heat	5	0	0	N/A
Extreme Precipitation	N/A	N/A	N/A	N/A
Sea Level Rise	1	0	0	N/A
Wildfire	1	0	0	N/A
Flooding	N/A	N/A	N/A	N/A
Drought	N/A	N/A	N/A	N/A
Snowpack Reduction	N/A	N/A	N/A	N/A
Air Quality Degradation	0	0	0	N/A

The sensitivity score reflects the extent to which a project would be adversely affected by exposure to a climate hazard. Exposure is rated on a scale of 1 to 5, with a score of 5 representing the greatest exposure.

The adaptive capacity of a project refers to its ability to manage and reduce vulnerabilities from projected climate hazards. Adaptive capacity is rated on a scale of 1 to 5, with a score of 5 representing the greatest ability to adapt.
The overall vulnerability scores are calculated based on the potential impacts and adaptive capacity assessments for each hazard. Scores do not include implementation of climate risk reduction measures.

6.3. Adjusted Climate Risk Scores

Climate Hazard	Exposure Score	Sensitivity Score	Adaptive Capacity Score	Vulnerability Score
Temperature and Extreme Heat	5	1	1	4
Extreme Precipitation	N/A	N/A	N/A	N/A
Sea Level Rise	1	1	1	2
Wildfire	1	1	1	2
Flooding	N/A	N/A	N/A	N/A
Drought	N/A	N/A	N/A	N/A
Snowpack Reduction	N/A	N/A	N/A	N/A
Air Quality Degradation	1	1	1	2

The sensitivity score reflects the extent to which a project would be adversely affected by exposure to a climate hazard. Exposure is rated on a scale of 1 to 5, with a score of 5 representing the greatest exposure.
The adaptive capacity of a project refers to its ability to manage and reduce vulnerabilities from projected climate hazards. Adaptive capacity is rated on a scale of 1 to 5, with a score of 5 representing the greatest ability to adapt.
The overall vulnerability scores are calculated based on the potential impacts and adaptive capacity assessments for each hazard. Scores include implementation of climate risk reduction measures.

6.4. Climate Risk Reduction Measures

7. Health and Equity Details

7.1. CalEnviroScreen 4.0 Scores

The maximum CalEnviroScreen score is 100. A high score (i.e., greater than 50) reflects a higher pollution burden compared to other census tracts in the state.

Indicator	Result for Project Census Tract
Exposure Indicators	—
AQ-Ozone	98.7
AQ-PM	4.43
AQ-DPM	1.14

Drinking Water	70.5
Lead Risk Housing	65.1
Pesticides	4.55
Toxic Releases	18.1
Traffic	3.04
Effect Indicators	—
CleanUp Sites	0.00
Groundwater	0.00
Haz Waste Facilities/Generators	1.80
Impaired Water Bodies	90.1
Solid Waste	75.7
Sensitive Population	—
Asthma	26.6
Cardio-vascular	44.6
Low Birth Weights	67.2
Socioeconomic Factor Indicators	—
Education	9.73
Housing	12.8
Linguistic	0.26
Poverty	55.9
Unemployment	35.0

7.2. Healthy Places Index Scores

The maximum Health Places Index score is 100. A high score (i.e., greater than 50) reflects healthier community conditions compared to other census tracts in the state.

Indicator	Result for Project Census Tract
Economic	—
Above Poverty	53.62504812

Employed	15.8475555
Median HI	38.16245348
Education	—
Bachelor's or higher	57.65430515
High school enrollment	0.372128834
Preschool enrollment	1.873476197
Transportation	—

7.3. Overall Health & Equity Scores

Metric	Result for Project Census Tract
CalEnviroScreen 4.0 Score for Project Location (a)	24.0
Healthy Places Index Score for Project Location (b)	21.0
Project Located in a Designated Disadvantaged Community (Senate Bill 535)	No
Project Located in a Low-Income Community (Assembly Bill 1550)	No
Project Located in a Community Air Protection Program Community (Assembly Bill 617)	No

a: The maximum CalEnviroScreen score is 100. A high score (i.e., greater than 50) reflects a higher pollution burden compared to other census tracts in the state.
b: The maximum Health Places Index score is 100. A high score (i.e., greater than 50) reflects healthier community conditions compared to other census tracts in the state.

7.4. Health & Equity Measures

No Health & Equity Measures selected.

7.5. Evaluation Scorecard

Health & Equity Evaluation Scorecard not completed.

7.6. Health & Equity Custom Measures

No Health & Equity Custom Measures created.

8. User Changes to Default Data
